Appendix N Revised IMM TIA *(Continued)*
Appendix O Itasca Clarification Memo
Appendix P NV5 Response Memo
Appendix Q Cemented Backfill Study
Appendix R Hexavalent Chromium and Nitrogen Dioxide HRA Memo

# 1. Introduction and List of Commenters

# 1. INTRODUCTION AND LIST OF COMMENTERS

## 1.1 INTRODUCTION

This Final Environmental Impact Report (EIR) contains agency and public comments received during the public review period of the Idaho-Maryland Mine Project (proposed project) Draft EIR (DEIR). This document has been prepared by Nevada County, as Lead Agency, in accordance with the California Environmental Quality Act (CEQA) and the CEQA Guidelines, Section 15132. The Introduction and List of Commenters chapter of the Final EIR discusses the background of the DEIR and purpose of the Final EIR, identifies the comment letters received on the DEIR, and provides an overview of the organization of the Final EIR.

## 1.2 BACKGROUND

The DEIR identifies the proposed project's potential environmental impacts and the mitigation measures that would be required to be implemented. The following environmental analysis chapters are contained in the DEIR:

- Aesthetics;
- Agriculture and Forestry Resources;
- Air Quality, Greenhouse Gas Emissions, and Energy;
- Biological Resources;
- Cultural and Tribal Cultural Resources;
- Geology, Soils, and Mineral Resources;
- Hazards and Hazardous Materials;
- Hydrology and Water Quality;
- Land Use and Population and Housing;
- Noise and Vibration;
- Public Services and Utilities;
- Transportation; and
- Wildfire.

In accordance with CEQA, the DEIR was sent to the State Clearinghouse (SCH# 2020070378) for distribution to State agencies. The public review period began on January 4, 2022 for a 60-day public review period, which was extended to April 4, 2022 for a total public review period of 91 days. In addition, the DEIR and Notice of Availability (NOA) for the DEIR were published on the Nevada County Community Development Agency website. Printed copies of the DEIR were made available for public review at the Nevada County Planning Department (950 Maidu Avenue, Suite 170, Nevada City, CA), as well as the following library locations: Madelyn Helling Library (980 Helling Way, Nevada City, CA); Grass Valley Library – Royce Branch (207 Mill Street, Grass Valley, CA); Penn Valley Library (11252 Pleasant Valley Road, Penn Valley, CA); and Truckee Library (10031 Levon Avenue, Truckee, CA). A Special Public Meeting before the Nevada County Planning Commission was held on March 24, 2022 to solicit public comments regarding the DEIR.

## 1.3 PURPOSE OF THE FINAL EIR

Under CEQA Guidelines Section 15132, the Final EIR shall consist of:

1. The DEIR or a revision of the DEIR.
2. Comments and recommendations received on the DEIR.
3. A list of persons, organizations, and public agencies commenting on the DEIR.
4. The responses to significant environmental points raised in the review process.
5. Any other information added by the Lead Agency.

As required by CEQA Guidelines, Section 15090(a)(1)-(3), a Lead Agency must make the following three determinations in certifying a Final EIR:

1. The Final EIR has been completed in compliance with CEQA.
2. The Final EIR was presented to the decision-making body of the Lead Agency, and the decision-making body reviewed and considered the information in the Final EIR prior to approving the project.
3. The Final EIR reflects the Lead Agency's independent judgment and analysis.

Under CEQA Guidelines Section 15091, a public agency shall not approve or carry out a project for which an EIR has been certified that identifies one or more significant environmental effects of the project unless the public agency makes one or more written findings (Findings of Fact) for each of those significant effects. Findings of Fact must be accompanied by a brief explanation of the rationale for each finding supported by substantial evidence in the record. The Findings of Fact are included in a separate document that will be considered for adoption by the County's decision-makers.

Pursuant to CEQA Guidelines, Section 15093(b), when a Lead Agency approves a project that would result in significant and unavoidable impacts, the agency must state in writing the reasons supporting the action (Statement of Overriding Considerations). The Statement of Overriding Considerations shall be supported by substantial evidence, and is subject to adoption by the County's decision-makers along with the Findings of Fact. The Idaho-Maryland Mine Project would result in significant and unavoidable impacts related to the following: substantially degrade the existing visual character or quality of the site and its surroundings (Impact 4.1-2); long-term changes in visual character (Impact 4.1-4); generation of a substantial temporary increase in ambient noise levels in the project vicinity (Impact 4.10-1); and conflicts with a program, plan, ordinance, or policy addressing study intersections (Impacts 4.12-1, 4.12-8, and 4.12-10). Thus, a Statement of Overriding Considerations must be adopted if the project is approved.

## 1.4 CRITERIA FOR RECIRCULATION

Pursuant to CEQA Guidelines Section 15088.5, Recirculation of an EIR Prior to Certification, a lead agency is required to recirculate an EIR when significant new information is added to the EIR after public notice is given of the availability of the draft EIR for public review under Section 15087 but before certification. New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect (including a feasible project alternative) that the project's proponents have declined to implement. Pursuant to 15088.5(a), "Significant new information" requiring recirculation include, for example, a disclosure showing that:

(1) A new significant environmental impact would result from the project or from a new mitigation measure proposed to be implemented.
(2) A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance.
(3) A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.
(4) The draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded. (*Mountain Lion Coalition v. Fish and Game Com.* (1989) 214 Cal.App.3d 1043)

The following discussion will evaluate the four above criteria and demonstrate that the changes to the DEIR text presented in Chapter 3 of this Final EIR do not require recirculation of the DEIR.

### 1. A new significant environmental impact would result from the project or from a new mitigation measure proposed to be implemented.

Pursuant to CEQA Guidelines Section 15088.5(b), recirculation is not required where the new information added to the EIR merely clarifies or amplifies or makes insignificant modifications in an adequate EIR. Chapter 3, Revisions to the Draft EIR Text, of this Final EIR includes several minor changes to the DEIR text as a result of public comment that serve the purpose of clarifying or amplifying the discussion in the EIR without identifying new significant impacts. The majority of modifications consist of small, targeted revisions, consisting of minor additions or deletions. A few modifications involve larger additions of text, but the relevant criterion is not the extent of the modification, but rather whether the added text identifies a new significant impact. For example, this Final EIR includes a new discussion of California spotted owl in Chapter 4.4, Biological Resources, of the DEIR, based on public comment and release of additional layers in California Department of Fish and Wildlife's BIOS database that confirmed previous spotted owl occurrences on the Brunswick Site. BIOS identifies four previous sightings of California spotted owl on the Brunswick Site, with a nest record from 2011 and non-nesting owl sightings in 2012, 2016, and 2018.

As discussed in Master Response 37 – Birds and Raptors, of this Final EIR, two California spotted owl surveys were conducted on the Brunswick Site in August 2022 pursuant to USFS protocol and no California spotted owl were detected. Further, Impact 4.4-2 of the DEIR already identifies that the Project could result in a significant impact to nesting raptors and other migratory bird species, and thus, includes Mitigation Measure 4.4-2(g) requiring a pre-construction survey for nesting raptors and migratory bird species prior to surface disturbance and avoidance and minimization measures in the event a species is identified. California spotted owl is considered a raptor, and while it was not specifically discussed in the DEIR, it is within the category of raptors for which the DEIR already identified a significant impact and required mitigation (MM 4.4-2(g)) protective of raptors. Nevertheless, for clarity, Mitigation Measure 4.4-2(g) has been revised to reference the California spotted owl by name and provide additional details regarding applicable survey methodology. The mitigation measure is not considerably different and the applicant has agreed to the revised mitigation measure (See #3 below). The above-described revisions to the EIR discussion and MM 4.4-2(g) do not result in a new significant environmental impact.

In response to public comment, this Final EIR also includes discussion in Chapter 4.4, Biological Resources, of riparian bird species. As discussed in Master Response 37, these riparian bird species were not detected on-site during field surveys and the DEIR already identifies that the Project could have a significant impact to nesting raptors and other migratory bird species, within which the riparian species would be included. DEIR Mitigation Measure 4.4-2(g) requires a pre-construction survey for nesting bird species prior to surface disturbance and avoidance and minimization measures in the event a species is identified. Therefore, the potential impact to these species has been analyzed and addressed in the DEIR. Nevertheless, for clarity, this Final EIR includes revisions to Chapter 4.4, Biological Resources, to include discussion of these riparian bird species and targeted revisions have been made to Mitigation Measure 4.4-2(g) to reference these species. These revisions to the EIR discussion and MM 4.4-2(g) do not result in a new significant environmental impact.

In response to public comment, it was also determined that the truck traffic percentages along study roadways needed to be updated in the transportation analysis. These corrections were made to the transportation analysis, an updated version of which is included as Appendix N to this Final EIR; and Chapter 4.12, Transportation, of the DEIR has been revised accordingly in this Final EIR. For example, Tables 4.12-2, 4.12-10, 4.12-11, 4.12-18, and 4.12-19 of the DEIR, reporting study intersection levels of service (LOS), and Tables 4.12-14, 4.12-15, 4.12-22, and 4.12-23 reporting study intersection queues, were updated in strike-through and underline format. However, as demonstrated in this Final EIR, in no case do the revisions trigger a new significant impact at study intersections, when comparing the updated values to the thresholds of significance used in the DEIR. Thus, these corrections do not warrant recirculation of the EIR.

As also shown above, the DEIR incorrectly used the Home-Based VTM per Worker, presented in Table A-3 of the SB743 Report,[1] as the threshold of significance for the project. The Total VMT per Service Population presented in Table A-4 should have been used as the threshold of significance in accordance with the Nevada County Traffic Impact Analysis Guidelines (June 2020). The northern portion of the Brunswick Site is partially in the Grass Valley sub-area and the southern portion is in the Unincorporated Western Nevada County subarea. The use of Total VMT per Service Population for Unincorporated Western Nevada County of 18.1 is the most conservative approach and the threshold of significance is 14.3% below the subarea mean with a value of 15.5 VMT per Service Population. As shown in updated Table 4.12-16, the proposed project is modeled to generate a daily rate per service population (employee) of 14.4 VMT, which is more than 14.3 percent below the unincorporated area metric of 18.1 VMT per worker (i.e., 15.5). Sections 4.12.2 and 4.12.4 of the DEIR have been updated to reflect these changes, as shown in Response to Comment Agcy 8-29. The above-noted errors, which are corrected in this Final EIR, did not affect the DEIR's conclusion related to the project's VMT impact in any way, which remains less than significant, as stated in the DEIR. As such, the above-described corrections to the EIR discussion did not result in a new significant environmental impact.

As discussed above, the remaining revisions to the DEIR, as presented in Chapter 3 of this Final EIR, are small, targeted revisions that serve to clarify or amplify the existing adequate DEIR. Many of these minor modifications pertain to mitigation language – see criterion #3 below. Please also refer to Chapter 3 for a review of those changes.

[1] The *Nevada County Transportation Commission Senate Bill 743 Final Vehicle Miles Traveled Implementation Report* (SB743 Report), 2020.

In summary, recirculation of the EIR is not required pursuant to criterion 1 of 15088.5, because no new significant environmental impact will result from the Project or its mitigation measures.

**2. A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance.**

This criterion pertains to whether the Final EIR provides significant new information showing that a substantial increase in the severity of an environmental impact already identified in the DEIR would occur unless mitigation measures are adopted that reduce the impact to a level of insignificance. Nothing in the responses to comments, nor in the changes to the DEIR text shown in Chapter 3 of this Final EIR, results in a substantial increase in the severity of a significant environmental impact identified in the DEIR. Recirculation of the EIR is not required under this criterion.

**3. A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.**

As shown in Chapter 3 of this Final EIR, as a result of public comment, several minor modifications are made to mitigation measures included in the DEIR. Under *Laurel Heights Improvement Ass'n v Regents of Univ. of Cal.* (1993) 6 C4th 1112 (*Laurel Heights II*) and 15088.5(a)(3), when information added to the Final EIR consists of a suggested new project alternative or mitigation measure, recirculation is only required if the new alternative or mitigation measure meets all of the following criteria:[2]

- It is feasible;
- It is considerably different from the alternatives or mitigation measures already evaluated in the Draft EIR;
- It would clearly lessen the project's significant environmental impacts; and
- It is not adopted.

Recirculation is only required if *each* of the above tests is met.

In all cases where this Final EIR makes modifications to mitigation measures included in the DEIR, the updated mitigation measures are feasible and the applicant has agreed to implement the updated mitigation measures. No new mitigation measures are identified in this Final EIR, only revised mitigation measures that are not considerably different from the mitigation measure language already included in the DEIR. Thus, this criterion is not triggered by the minor modifications to mitigation measures and recirculation of the EIR is not required.

With respect to the portion of the comment pertaining to alternatives, several commenters suggested one or more additional alternatives for the County to consider. As discussed in this Final EIR, Section 6 of the DEIR considered project alternatives. As summarized in DEIR

[2] Stephen L. Kostka and Michael H. Zischke. *Practice Under the California Environmental Quality Act, Second Edition, March 2022 Update, Volume 2*. March 2022, pg. 16-21.

Section 6.2, and provided in CEQA Guidelines Section 15126.6, an EIR shall provide a reasonable range of alternatives that achieves the project objectives but avoids or reduces significant project impacts. The alternatives analysis is not required to consider every project alternative but is governed by a "rule of reason" that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice." The alternative analysis in the DEIR considered nine different alternatives. Five alternatives were considered but rejected from detailed analysis since they did not meet most project objectives, were infeasible, and/or did not avoid significant project impacts. Four alternatives were analyzed in detail (see DEIR section 6.3.) The County believes this provides a reasoned choice of alternatives for consideration by the public and decisionmakers. This Final EIR demonstrates how the alternatives proposed by the commenters are either not considerably different from others previously analyzed in that they are not anticipated to eliminate any of the significant impacts of the Project, and/or they are not feasible. Thus, this criterion is not triggered and recirculation of the EIR is not required.

**4. The draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded.**

According to Kostka and Zischke, this test for recirculation is based on the type of wholesale omission of information found in *Mountain Lion Coalition v. Fish & Game Comm'n*, in which the Draft EIR omitted any analysis of cumulative impacts, and a detailed analysis was first provided in the final EIR.[3] The record clearly demonstrates that no such wholesale omissions have occurred with the Idaho-Maryland Mine DEIR.

## 1.5 LIST OF COMMENTERS

Nevada County received 12 comment letters from agencies, 32 letters from groups, and 2,821 individual comment letters during the public comment period on the DEIR for the proposed project. In addition, verbal comments were received at the Special Public Meeting, and six comment letters were received after the close of the public comment period. For efficiency and clarity, the comment letters have been organized into 10 distinct categories: Agency Letters; Group Letters; Form Letter A; Form Letter B; Form Letter C; Form Letter D; Support Cards; Individual Letters; Late Letters; and DEIR Meeting. Many of the comment letters received contained template language, and, thus, were categorized into groups of "Form Letters". Form Letters A and B contain a space for commenters to include their individualized comments; however, Form Letters C and D and the Support Cards contain the template language only. This Final EIR includes all comment letters received, including duplicate letters authored by the same individual(s), but sent to multiple recipients. Some agencies, groups, and/or individuals submitted multiple letters, and, as a result, their name appears multiple times in the tables below. The comment letters were authored by the following:

### Agencies

| Letter Number | Author(s) | | Agency |
|---|---|---|---|
| | First Name | Last Name | |
| Agency 1 | Daniel | Lubin | California Department of Parks and Recreation |
| Agency 2 | Kevin | Yount | California Department of Transportation |

### Special Public Meeting

A transcript of the verbal comments received at the Special Public Meeting on the DEIR is included in this Final EIR and is identified as comment letter "DEIR Meeting."

## 1.6 ORGANIZATION OF THE FINAL EIR

The Final EIR is organized into the following chapters:

### 1. Introduction and List of Commenters

Chapter 1 provides an introduction and overview of the document, describing the background and organization of the Final EIR. Chapter 1 also provides a list of commenters who submitted letters in response to the DEIR.

### 2. Responses to Comments

Chapter 2 presents the comment letters received and responses to each comment. Each comment letter received has been numbered at the top and bracketed to indicate how the letter has been divided into individual comments. Each comment is given a number with the letter number appearing first, followed by the comment number. As noted above, for efficiency and clarity, the comment letters have been organized into 10 distinct categories: Agency Letters; Group Letters;

Form Letter A; Form Letter B; Form Letter C; Form Letter D; Support Cards; Individual Letters; Late Letters; and DEIR Meeting. Therefore, the letter number will correspond to the category (i.e., the first agency letter would be numbered Agency Letter 1), and the first comment in Agency Letter 1 would have the following format: Agcy 1-1. For further example and clarification, the first comment in Group Letter 1 would be numbered Grp 1-1; the first comment in Form Letter A 1 would be A 1-1; the first comment in Form Letter B 1 would be B 1-1; the first comment in Form Letter C 1 would be C 1-1; the first comment in Form Letter D would be D 1-1; the first comment in Support Card 1 would be Sup 1-1; the first comment in Individual Letter 1 would be Ind 1-1; the first comment in Late Letter 1 would be Lt 1-1; and the first comment in the DEIR Meeting transcript would be Meet-1. The response to each comment will reference the comment number.

## 3. Revisions to the DEIR Text

Chapter 3 summarizes minor changes made to the DEIR text since its release.

## 4. Mitigation Monitoring and Reporting Program

CEQA Guidelines, Section 15097, requires lead agencies to adopt a program for monitoring the mitigation measures required to avoid the significant environmental impacts of a project. The intent of the Mitigation Monitoring and Reporting Program (MMRP) is to ensure implementation of the mitigation measures identified within the EIR for the proposed project.

# 2. Responses to Comments

# 2. RESPONSES TO COMMENTS

## 2.1 INTRODUCTION

The Responses to Comments chapter contains responses to each of the comment letters submitted regarding the proposed project DEIR during the public review period, as well as responses to the verbal comments received at the hearing to receive public comment.

## 2.2 MASTER RESPONSES

Many of the commenters raised similar concerns. For such concerns, the County has prepared a master response. Through master responses, the County can address the common topics in a comprehensive manner and without duplication in the individual responses. Some of the thematic comments submitted on the DEIR pertain to issues that are not considered significant impacts on the environment under CEQA, as will be discussed in Master Responses 1, 2, and 3. Such issues include administrative issues, social and economic impacts, and responsibilities of the Project Applicant. A number of thematic comments regarding the technical analysis of the DEIR were also submitted and are addressed through the remaining Master Responses presented below.

The responses amplify or clarify information provided in the DEIR and/or refer the reader to the appropriate place in the document where the requested information can be found. Where revisions to the DEIR text are required in response to the comments, such revisions are noted in the response to the comment, and are also listed in Chapter 3 of this Final EIR. All new text is shown as <u>double underlined</u> and deleted text is shown as ~~struck through~~.

The changes to the analysis contained in the DEIR represent only minor clarifications/amplifications and do not constitute significant new information. In accordance with CEQA Guidelines, Section 15088.5, recirculation of the DEIR is not required, as discussed in detail in Chapter 1 of this Final EIR.

### Master Response 1 - Non-EIR/Administrative Issues

#### Comments

The CEQA Guidelines frame the scope and focus of review and the extent, nature and scope of responses by a lead agency to comments on a DEIR. This Final EIR addresses both comments pertaining to impacts analyses and acknowledges comments not related to environmental impact and analysis. However, other comments received, continued the commenter's opinion on approval or denial, how the Project could affect the commenter's perceived "quality of life," and/or concerns regarding changes in property value. This section provides a response to these types of comments, which are either general or unrelated to the Project's impacts on the physical environment.

#### Discussion

**15204. FOCUS OF REVIEW**

(a) In reviewing draft EIRs, persons and public agencies should focus on the sufficiency of the document in identifying and analyzing the possible impacts on

> the environment and ways in which the significant effects of the project might be avoided or mitigated. Comments are most helpful when they suggest additional specific alternatives or mitigation measures that would provide better ways to avoid or mitigate the significant environmental effects. At the same time, reviewers should be aware that the adequacy of an EIR is determined in terms of what is reasonably feasible, in light of factors such as the magnitude of the project at issue, the severity of its likely environmental impacts, and the geographic scope of the project. CEQA does not require a lead agency to conduct every test or perform all research, study, and experimentation recommended or demanded by commentors. When responding to comments, lead agencies need only respond to significant environmental issues and do not need to provide all information requested by reviewers, as long as a good faith effort at full disclosure is made in the EIR.
>
> (c) Reviewers should explain the basis for their comments, and should submit data or references offering facts, reasonable assumptions based on facts, or expert opinion supported by facts in support of the comments. Pursuant to Section 15064, an effect shall not be considered significant in the absence of substantial evidence.

Notwithstanding the above guidelines language, CEQA Guidelines section 15204(e) states that these limitations should "not be used to restrict the ability of reviewers to comment on the general adequacy of a document or of the lead agency to reject comments not focused as recommended by this section."

## Oppose/Support Project

Commenters voiced general opposition to or support for the Project. Often these comments were combined with other general statements about environmental concerns (e.g., air quality, traffic, noise). According to CEQA Guidelines section 15088, "The level of detail contained in the response, however, may correspond to the level of detail provided in the comment (i.e., responses to general comments may be general). A general response may be appropriate when a comment does not contain or specifically refer to readily available information, or does not explain the relevance of evidence submitted with the comment." Thus, when a commenter expresses general concerns like the proposed project would result in "more traffic", "increased air pollution", "effects on water quality", or "increased noise", a specific response is not offered. Rather, the commenter is referred to those sections of the DEIR where the referenced general concern is evaluated in detail. For example, project-related traffic and its effect on the regional roadway network is evaluated in Chapter 4.12, Transportation, of the DEIR. The project-related increase in air quality emissions and their effect on the surrounding environment, including human health, is addressed in Chapter 4.3, Air Quality and Greenhouse Gas Emissions. The potential effects of the project on local hydrology and water quality, including groundwater, are addressed in Chapter 4.8, Hydrology and Water Quality, of the DEIR, and potential impacts related to noise and vibration associated with construction and operation of the proposed project are addressed in Chapter 4.10, Noise and Vibration, of the DEIR. Etc.

The environmental review process provides an impartial evaluation of the environmental impacts should the Project be implemented and not opinions on whether the Project should be approved or denied. The County Planning Department, as the public agency with land use authority, is the primary agency providing information and recommendations on land development to the Planning Commission and Board of Supervisors. The decision-makers, typically the Planning Commission and/or Board of Supervisors, weigh factors outside the scope of the EIR, including public support,

taxes, jobs, economic benefits, and other non-environmental factors, in considering approval of a Project.

Those comments in support/opposition do not concern environmental impacts; therefore, they are hereby noted and referred to the decision-makers for consideration in their deliberations for approval or denial of the Project.

## Quality of Life

Other comment letters opposed the proposed project because it would allegedly affect the rural nature of the community or otherwise negatively affect residents' perceived current quality of life.

In enacting CEQA, the California Legislature declared policies explaining its intent. Included were:

> Public Resources Code, §21000-21001:
> - The maintenance of a quality environment for the people of this state now and in the future is a matter of statewide concern.
> - It is necessary to provide a high-quality environment that at all times is healthful and pleasing to the senses and intellect of man.
> - The capacity of the environment is limited, and it is the intent of the Legislature that the government of the state take immediate steps to identify any critical thresholds for the health and safety of the people of the state and take all coordinated actions necessary to prevent such thresholds being reached.
> - Create and maintain conditions under which man and nature can exist in productive harmony to fulfill the social and economic requirements of present and future generations.

The EIR process undertaken by the County has been accomplished in a manner consistent with the CEQA statute and guidelines. CEQA is not a tool to forestall any and all changes to the environment, but rather to establish thresholds and manage such changes accordingly, while meeting the economic requirements and needs of the community.

To this end, the CEQA statute and guidelines confirm that environmental needs must at times be secondary to economic and social needs, and authorized lead agencies, after considering the environmental consequences, to approve projects in spite of one or more significant effects:

> Public Resources Code, §21002:
> The Legislature finds and declares that it is the policy of the state that public agencies should not approve projects as proposed if there are feasible alternatives or feasible mitigation measures available which would substantially lessen the significant environmental effects of such projects, and that the procedures required by this division are intended to assist public agencies in systematically identifying both the significant effects of proposed projects and the feasible alternatives or feasible mitigation measures which will avoid or substantially lessen such significant effects. The Legislature further finds and declares that in the event specific economic, social, or other conditions make infeasible such project alternatives or such mitigation measures, individual projects may be approved in spite of one or more significant effects thereof.

Thus, CEQA considers issues related to quality of life and acknowledges that a project may be approved despite environmental effects. The environmental review process focuses on physical impacts to the environment. Therefore, quality of life comments are hereby noted and referred to the decisionmakers for consideration in their deliberations for approval or denial of the Project.

### Economic Effect on Property Values

Some comment letters questioned whether permitting the Project would reduce property values of surrounding lands. Because CEQA is primarily concerned with physical changes in the environment, economic effects alone do not trigger a finding of a substantial impact under CEQA; "[T]here must be a physical change resulting from the project directly or indirectly before CEQA will apply." Such changes can be direct or indirect. Economic and social impacts of a proposed project "shall not be treated as significant effects on the environment" (CEQA Guidelines §15131(a) (emphasis added). In other words, if a proposed project may cause economic and social consequences, but no significant environmental impacts, CEQA does not require that an EIR be prepared.

The courts have specifically rejected consideration of economic concerns unless the Project's economic impact would cause changes to the physical environment such as blight. For example, courts have held that "the economic impact of small businesses on property values" did not trigger CEQA review in City of Orange v. Valenti (4th Dist. 1974) 37 Cal. App. 3d 240, 249 [112 Cal. Rptr. 379]. Please also refer to Master Response 2.

Where an EIR does identify significant environmental effects, however, related economic and social impacts are not irrelevant. For example:

> CEQA Guidelines, §15131(a):
> "An EIR may trace a chain of cause and effect from a proposed decision on a project through anticipated economic or social changes resulting from the project to physical changes caused in turn by the economic and social changes. The intermediate economic and social changes need not be analyzed in any detail greater than necessary to trace the chain of cause and effect. The focus of the analysis shall be on the physical changes."

Indirect off-site impacts associated with the Project are limited; the EIR clearly identifies such effects. There is no evidence that physical effects to other properties would occur that could result in reduction of property values, or that if such reduction in property values happened to occur, such reduced values would result in physical effects subject to CEQA review. Comments regarding the project's potential to affect property values are hereby noted and referred to the decision-makers for consideration in their deliberations for approval or denial of the Project.

### Conclusion

Pursuant to the CEQA Guidelines, in reviewing draft EIRs, persons and public agencies should focus on the sufficiency of the document in identifying and analyzing the possible impacts on the environment and ways in which the significant effects of the project might be avoided or mitigated. When responding to comments, lead agencies need only respond to significant environmental issues. This master response recognizes that many public comments submitted on the Idaho-Maryland Mine DEIR are outside of the scope of CEQA; and thus, do not require a specific response from the County. Nevertheless, this Final EIR includes all comments for the record and review and consideration by the decisionmakers.

## Master Response 2 - Social and Economic Impacts

### Comments

Select comments submitted on the DEIR state that the project would result in social or economic impacts, such as potentially having an effect on neighboring property values.

## Discussion

The scope of an EIR is limited to a local agency's evaluation of potentially significant environmental impacts of a project, which by definition are limited to physical conditions, rather than social or economic conditions. (Pub. Res. Code § 21060.5; CEQA Guidelines § 15360.) The analysis of social or economic impacts unrelated to a physical change is not included within an EIR because such potential impacts are not considered to be effects on the environment. (CEQA Guidelines §§ 15064(e), 15131(a), 15358(b), 15382.) Therefore, potential social or economic impacts that do not contribute to, or are not caused by, physical impacts on the environment, are not substantial evidence of a significant environmental effect. (Pub. Res. Code § 21080(e)(2); CEQA Guidelines § 15064(f)(6).)

California courts have routinely dismissed challenges to projects under CEQA when premised on potential social or economic impacts. (see*, e.g.*, *Clews Land & Livestock, LLC v. City of San Diego* (2017) 19 Cal.App.5th 161, 196 [potential effect of project's noise on nearby business's economic viability not reviewable under CEQA]; *Chico Advocates for a Responsible Economy v. City of Chico* (2019) 40 Cal.App.5th 839, 846–48 [loss of close and convenient shopping not an environmental issue subject to CEQA review]; *City of Hayward v. Board of Trustees of the California State University* (2015) 242 Cal.App.4th 833, 840–47 [project's potential economic impacts on costs of providing public services not a cognizable environmental impact under CEQA]; *Maintain Our Desert Environment v. Town of Apple Valley* (2004) 124 Cal.App.4th 430, 446 ["[S]ocial, economic and business competition concerns are not relevant to CEQA analysis unless it is demonstrated that those concerns will have a significant effect on the physical environment."]; *Preserve Poway v. City of Poway* (2016) 245 Cal.App.4th 560, 576–82 [change in community character is a social and psychological impact not reviewable under CEQA].)

More specifically, courts have dismissed CEQA challenges that are based on an assertion that a project will have an adverse impact on nearby property values. For example, in *Porterville Citizens for Responsible Hillside Development v. City of Porterville* (2007) 157 Cal.App.4th 885, neighboring landowners expressed concern that a housing project would have the effect of lowering their property values. The Court of Appeal held that such concerns were not reviewable under CEQA and were not substantial evidence of an environmental effect. The Court confirmed:

> CEQA is not an economic protection statute. Landowners surrounding a proposed project site do not state a valid CEQA concern when they express fears that the proposed project could adversely affect their property value.

(*Porterville Citizens*, 157 Cal.App.4th at 903 [citing *Bakersfield Citizens for Local Control v. City of Bakersfield* (2004) 124 Cal.App.4th 1184, 1205 *and* CEQA Guidelines § 15131(a)].) The California Supreme Court subsequently denied review of the *Porterville Citizens* decision. Therefore, the court's holding remains valid and no CEQA concerns have been raised. Additionally

in *Gray v. County of Madera* (2008) 167 Cal.App.4th 1099, the Court of Appeal came to a similar conclusion in evaluating neighboring landowners' claims that a hard rock quarry project would cause economic impacts to their property values because of the potential impact of the mine project on water levels in the landowners' private wells. The Court held that the landowners had raised merely economic and social concerns, the claimed impacts were not physical changes to the environment, and thus the concerns were not evidence to be considered in connection with the environmental review of the project under CEQA. (*Gray*, 167 Cal.App.4th at 1120–21.)

### Conclusion
As such, comments concerning potential social or economic effects of the project, when not contributing to, or when not caused by, a physical change to the environment, need not be analyzed or addressed further in this EIR.

## Master Response 3 - Operator Responsibility

### Comments
The County has received several comments stating that the Project should not be approved due to the past record of Rise Gold and its CEO, Ben Mossman. Specifically, the commenters allege that Rise Gold will fail to comply with its conditions of approval and will operate the mine in an illegal manner, causing harm to the community and the environment.

### Discussion
These comments do not raise an issue relevant to CEQA analysis, as the possibility of non-compliance with conditions of approval or mitigation measures is not considered an environmental impact under CEQA. Moreover, the County has ample authority to revoke the Project's permits if the operator does not comply with the required mitigation measures and conditions of approval. The County will also continue to monitor the project through implementation of CEQA mitigation monitoring. Specifically, County Code Section L-II 5.11 states that the County may revoke a use permit or other permit for the following reasons:

1. Non-compliance with conditions of approval, mitigation measures or the approved site plan.
2. Violation of any law in connection with the permit.
3. Expansion of the use or structure without amending the existing permit or receiving a new permit.
4. Operating in a manner that threatens or is injurious to the public health or safety, or constitutes a nuisance.
5. The permit was issued, in whole or in part, on the basis of a misrepresentation or omission of a material statement in the application, or in the applicant's testimony presented during the public hearing, for the permit.
6. Circumstances under which the permit was granted have been changed by the applicant to a degree that one or more of the findings contained in the original permit can no longer be made and the public health, safety, and welfare require the revocation.

As such, in the event that the mine operator fails to comply with its mitigation measures or conditions of approval, the County would initiate proceedings to revoke its permit. If the County revoked the use permit for the mine due to non-compliance with permit requirements, the mine could no longer operate.

While the commenter's concerns are not a CEQA environmental issue for purposes of the EIR, Mr. Mossman provided background information on a discharge incident at a previously operated mine in Canada, which summary is set forth below:

> Benjamin Mossman was a director and officer of Banks Island Gold Ltd. ("Banks"), a company formerly listed on the TSX Venture Exchange that traded under the symbol "BOZ". Banks operated the Yellow Giant Gold Mine (the "Mine") located in British Columbia, Canada. In 2015, unusually heavy rains occurred at the Mine site, which caused an alleged discharge to occur on a small portion of the site. Mr. Mossman was not at the

site at the time the alleged discharge occurred. Further, as soon as Mr. Mossman was made aware of the alleged discharge, he ordered that the incident be reported. Mr. Mossman cooperated with authorities throughout the investigation process.

Despite British Columbia's Chief Inspector of Mines', Al Hoffman, statement that he does not think the discharge is that serious (see Times Colonist, "Yellow Giant Gold Mine Spill Sparks Investigation" (July 29, 2015), https://www.timescolonist.com/news/b-c/yellow-giant-gold-mine-spill-sparks-investigation-1.2015061), Mr. Mossman, Banks, and two other former employees of Banks, were subject to summary conviction proceedings commenced in August 2016 for alleged violations of the British Columbia provincial Environmental Management Act (the "EMA"), the provincial Water Act, and the federal Fisheries Act. The court found Mr. Mossman not guilty and acquitted him of all charges, including pollution-related charges, but found Mr. Mossman guilty of two minor administrative charges. More specifically, Mr. Mossman was only found guilty of charges for failing to call each of the provincial and federal phone numbers (respectively) required to be called when an incident occurred that was required to be called under those statutes. For those two minor offences, the court imposed a $15,000 fine against Mr. Mossman.

Subsequent to the decision, the Crown appealed certain aspects of the trial judge's findings as they related to Mr. Mossman. The summary conviction appeal was heard by the BC Supreme Court in May 2019. In February 2020, the court set aside the two minor convictions against Mr. Mossman, but also ordered a new trial in the matter. The reasons behind the court's order for a new trial related to a disagreement on the admissibility of certain evidence. The new trial has not yet been scheduled but is currently forecasted to start sometime in 2022.

In a separate but concurrent trial involving the same incidents as the first, the Crown charged Mr. Mossman with obstruction of justice related to the investigation of the underlying EMA-related charges. After a full trial, the court acquitted him of that charge on March 6, 2019. More importantly, the Court made affirmative findings of fact that could support innocence in that trial, which included confirmation that Mr. Mossman was not at the site at the time of the alleged discharge and Mr. Mossman ordered that the incident be reported. The Crown did not appeal that acquittal.

It is worthy to note that the Mine is not currently closed for environmental reasons. Rather, the Mine is closed due to a change in Canadian law which effectively requires the Tribal Nation's consent for permitting and operations. The Mine property is now owned by MCC Canadian Gold Ventures, who is currently seeking the consent of the Tribal Nation to reopen the Mine.

### Conclusion

Comments related to Rise Gold's past record and concerns that said record suggests the applicant will operate the Idaho-Maryland Mine in an illegal manner are outside the scope of CEQA. Moreover, the County has ample authority to revoke the Project's permits if the operator does not comply with the required mitigation measures and conditions of approval. The County will also continue to monitor the project through implementation of CEQA mitigation monitoring.

## Master Response 4 - Cleanup Project is a Separate Project Under CEQA

### Comments

The County has received numerous comments asserting that the Idaho Maryland Mine Project ("IMM Project") should be analyzed in combination with the Centennial Industrial Site Clean-Up Project ("Clean-Up Project") as a single project for CEQA purposes. Some of the various

commenters asserted that the Centennial Industrial Site is only being remediated for the purpose of accepting engineered fill from the IMM Project, and that the Idaho Maryland Mine Project cannot proceed without the Clean-Up Project. Accordingly, several commenters argue that the impacts associated with the clean-up project must be analyzed in the EIR for the Idaho Maryland Mine Project. On the Contrary, the Clean-Up Project is a separate Project to remediate site conditions including the presence of lead, asbestos, mercury and other metals, as mandated by the U.S. EPA.

## Discussion

First, as a preliminary matter, the Idaho Maryland Mine Project is designed to proceed whether the DTSC clean-up project is completed or is not completed. If the DTSC clean-up project is completed, the Project is designed such that engineered fill will be transported to the Centennial Industrial Site and used to create useable land for future uses consistent with the applicable zoning. Conversely, if the DTSC clean-up project is not completed within the life of the Project, rock material from the Project that would have been transported to the Centennial Industrial Site, instead would be sold in the regional market as construction aggregate.

Second, the Clean-Up Project is a separate project from the IMM Project that is independently necessary to remediate site conditions caused by historic operations on the Centennial Industrial Site. The reason for the Clean-Up Project was the identification of the Centennial Industrial Site by the U.S. EPA as potentially requiring environmental cleanup and the later coordination between the property owner and the DTSC to implement a remedial action plan to remediate lead, arsenic, mercury and other metals found onsite. The U.S. EPA first performed a preliminary analysis on the Centennial Industrial Site in June of 2002, nearly two decades before the IMM Project was proposed, and before the IMM Project Site was owned by the current owner. Based on the report from 2002, the U.S. EPA recommended that further assessment was necessary under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). The U.S. EPA subsequently performed additional assessments of the Centennial Industrial Site in 2005, 2011, 2018 and 2019. Discussions regarding cleanup of the Centennial Industrial Site began between the U.S. EPA, the DTSC and the site owner prior to any application for the IMM Project having been submitted. As the Centennial Industrial Site has been targeted by the U.S. EPA for cleanup since 2002, and discussions regarding cleanup of the Project site were well underway before the IMM Project application was submitted, statements from commenters that the Project is merely a component of a larger plan to develop an underground gold mine (the IMM Project), is factually incorrect. Third, the Clean-Up Project is under the authority of the California Department of Toxic Substances Control.

### Case Law Supports the Separation of the Current Project and the Clean-Up Project for CEQA Purposes

California courts do not consider distinct activities as one CEQA project required to be reviewed together, except in two situations: 1) When the purpose of the project under review is to provide the necessary first step toward a larger development; and 2) When development of the project under review requires or presumes completion of another activity. (*Banning Ranch Conservancy v. City of Newport Beach* (2012) 211 Cal.App.4th 1209, 1223). Further, California courts have been clear that even related projects are not required to be analyzed as one project where each project has independent utility, serves a different purpose, or can be implemented independently from the completion of the related activity. (Id. at pp. 1223-1224, citing *Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70, 99 [refinery upgrade and construction of pipeline exporting excess hydrogen from upgraded refinery were "independently justified separate projects with different project proponents"]; *Planning & Conservation League v.*

*Castaic Lake Water Agency* (2009) 180 Cal.App.4th 210, 237 [water transfer had "significant independent or local utility" from broader water supply agreement, and would be implemented with or without it]; *Sierra Club v. West Side Irrigation District* (2005) 128 Cal.App.4th 690, 699 [two water-rights assignments to city were "approved by different independent agencies" and "could be implemented independently of each other].)

The Clean-Up Project and the IMM Project each have independent utility, each serve a different purpose, and each can be implemented independently from the completion of the other. The utility and purpose of the Clean-Up Project is to ensure timely and efficient cleanup of the Centennial Industrial Site due to existing site conditions, and is required under both California and federal environmental regulations—not because it would benefit the IMM Project. The separate Clean-Up Project is necessary whether or not the IMM Project is approved by Nevada County. Consequently, under the holding in Banning Ranch, the Clean-Up Project should be analyzed separately from the IMM Project under CEQA. (see Banning Ranch, supra, at pp. 1223-1224.)

Conversely, the utility and purpose of the IMM Project is to allow for exploration and development of underground natural resources, and the IMM Project does not help nor hinder the environmental cleanup of the Centennial Industrial Site proposed as a separate DTSC project. The IMM Project's option to place engineered fill on the Centennial Industrial Site is not for environmental cleanup purposes, but for the purpose of creating usable industrial land on that property and for disposal of waste rock from the underground mine. While it is true that if the Clean-Up Project is not approved by the DTSC, the waste rock from the IMM Project cannot be placed on the Centennial M-1 property, the IMM Project can nonetheless proceed. As such, the IMM Project also satisfies the holding in Banning Ranch, such that it has independent utility, serves a different purpose, and can be implemented independently from the completion of the Clean-Up Project. Accordingly, the Clean-Up Project should be reviewed separately from the IMM Project under California law.

Notably, California courts have already addressed a similar situation relating to environmental cleanup activities that were not yet completed but were assumed to be completed prior to a development project on Treasure Island within San Francisco. (*Citizens for a Sustainable Treasure Island v. City and County of San Francisco* (2014) 227 Cal.App.4th 1036.) In *Citizens for a Sustainable Treasure Island*, San Francisco approved a project that included "a new, mixed-use community, including up to 8,000 residential units … up to 140,000 square feet of new commercial and retail space; up to 100,000 square feet of new office space; restoration and reuse of historic buildings on Treasure Island; about 500 hotel rooms; public utilities; 300 acres of parks, playgrounds, and public open space; bike and transit facilities; and a new ferry terminal and intermodal transit hub." (Id. at 1044.) The project site (Treasure Island) in that case was known to have extensive contamination with hazardous materials; however, cleanup had not yet been completed at the time of that project's approval. (Id. at 1056.) As stated by the court, "the 'operating assumption' is that the Navy will complete the cleanup before the property is conveyed to the City." (Id.)

However, the appellant in *Citizens for a Sustainable Treasure Island* asserted that the EIR in that case was deficient because it "provides no project-level details as to precisely where, when or to what extent [remediation] activities may be required … [and that the] City unlawfully deferred the development and adoption of mitigation measures for significant, adverse impacts resulting from the disturbance of contaminated soil and groundwater...." (Id. at 1057.) The Appellant did not prevail and the Court rejected these claims. The court ultimately concluded that the EIR in that case was adequate and had appropriately relied on an assumption that the Navy would clean up the site consistent with applicable laws and regulations. (Id. at 1060.) Further the court rejected

the argument that the EIR in that case was required to specifically analyze the clean-up activities under the separate authority of the Navy. (Id. at 1056-1061.) Similar to the situation in *Citizens for a Sustainable Treasure Island,* the Idaho Maryland Mine Project's DEIR identifies the separate clean-up project, acknowledges that the clean-up project is under the authority of the DTSC and reasonably concludes that such cleanup would be completed prior to implementation of the Project on the Centennial Site. Further, taking an even more conservative approach than the EIR in *Citizens for a Sustainable Treasure Island,* the Project's DEIR acknowledges that Project activities would not be allowed on the Centennial Site if the DTSC cleanup project is not completed. [Draft a Conclusion]

### Use of Electric Vehicles to Haul Engineered Fill Should It Be Necessary to Transport Fill to Locations other than Centennial Prior to 2033

Several commenters argued that the DEIR did not adequately address the Project's air quality impacts that would occur in the situation where the Centennial Site clean-up is not completed within the life of the Project and sale of waste rock and sand tailings were to occur sooner than anticipated. The DEIR analyzed the impacts of off-site hauling of rock material to the construction aggregate market, starting in 2033; however, it was assumed that prior to 2033, rock material would be placed on the Brunswick engineered fill pile and Centennial Site engineered fill pile. Based on public comments regarding the air quality and GHG impacts associated with hauling of rock material to construction aggregate purchasers earlier than anticipated, the applicant has agreed to a condition of approval that would require the applicant to use electric trucks for any offsite sale or transport of waste rock or sand tailings from the Brunswick site (other than to the Centennial Site) if such transport occurs prior to 2033. Hauling of material to offsite locations for use as construction aggregate starting in 2033 was already assumed in the DEIR's analysis; thus, the emissions impacts associated with this activity are already included in the DEIR, regardless of whether the Centennial Site is available for placement of fill material. The below condition would ensure that the Project would not have greater air quality and GHG emissions impacts than analyzed under the DEIR even if the Centennial Site is not available for placement of engineered fill. The text of the condition of approval is provided below:

> In the event that sand tailings or waste rock material is transported from the Brunswick Site prior to 2033 to locations other than the Centennial Site, all transport of such material shall be accomplished using electric vehicles.

### Conclusion

The Clean-Up Project is a separate project from the IMM Project that is independently necessary to remediate site conditions caused by historic operations on the Centennial Industrial Site. The Idaho-Maryland Mine Project is designed to proceed whether the DTSC clean-up project is completed or is not completed. This Final EIR demonstrates that, should it be necessary to transport engineered fill to locations other than the Centennial Site prior to 2033, additional air emissions would not result from such hauling activities, as only electric haul vehicles would be utilized.

## Master Response 5 - Evacuation Zones

### Comments

Several commenters asserted that the Project's traffic, in particular haul trucks, could have impacts related to substantially impairing emergency evacuation of the areas surrounding the project sites, particularly in the event of a wildfire.

## Discussion

These concerns are related to Appendix G Section IX(f) and Section XX(a). The DEIR evaluates these topics in Impacts 4.7-4 (Hazards) and 4.13-1 (Wildfire). As discussed below, project traffic and project employee vehicles exiting the project site during a mandatory evacuation represent a small percentage of existing traffic on the relevant evacuation routes, would be subject to the same traffic controls, and therefore would not cause any impact to the community's use of evacuation routes.

### Available Evacuation Routes

The Brunswick Industrial Site is located in evacuation Zone NCO-E188 and the Centennial Industrial Site is location in Zone GRS-E222 (see Map 4 of Evaczonemaps).

The Centennial Site would only have 4 employees onsite for approximately 5 years of the project life. Given the insignificant number of employee vehicles the Centennial site is not discussed further in the regards to a potential wildfire evacuation.

The Brunswick Site is located at the junction of Brunswick Road, E. Bennett Road, and Greenhorn Road. Commenters have expressed concern about employees at the Brunswick Site interfering with a potential evacuation of residents living east of the project in the Greenhorn Road area. These areas are in Zones NCO-E189 (see Map 4) and Zone NCO-E184 (see Map 6). Approximately 810 parcels are located in this area (see Figure 1 and Table 1 below). There are two roadways from which residents could evacuate; westbound via Greenhorn Road to the intersection of Greenhorn, Brunswick, and East (E.) Bennett Roads (see Figure 2 below) or northbound via Jones Ridge Road to Banner Lava Cap Road (see Figure 3 below).

Evacuation via Jones Ridge Road routes traffic away from the project site and numerous routes to the highway are available once vehicles reach Banner Lava Cap Road including:

1) West on Banner Lava Cap Road to highway
2) West on Banner Lava Cap Road, West on Idaho-Maryland Road, North on Brunswick Road to highway
3) East Banner Quaker Hill Road, West on Quaker Hill Cross Road, West on Red Dog Road to highway

Any evacuation from Banner Mountain would also have access to these routes (see Figure 4 below).

### Project Traffic Along Evacuation Routes

The only possible interference from the project's traffic would be on the segment of Brunswick Road if evacuees chose this route. Project traffic on Brunswick Road would be from trucking (6:00AM to 10:00PM) and employees during shift change. One-way truck trips would average 50 per day with a maximum of 100 per day. (see DEIR p. 3-26.) Over 16 hours, this equates to a truck passing through Brunswick Road, in either direction, approximately 6 times per hour on average. The normal volume of traffic on this roadway from 6:00AM to 10:00PM ranges from approximately 100 to 1,300 vehicles per hour and is typically 1,000 or more vehicles per hour from 7:00AM to 6:00PM (see pages to 431 - 458 of Appendix O to the DEIR). Therefore, the project truck traffic accounts for only approximately 1% of typical traffic. Approximately 20% of employees are estimated to use this segment of Brunswick Road (see Figure 6a of Appendix O to the DEIR). The largest shift change is at 7:00AM on weekdays where a total of 174 employees would be coming to or leaving from work and 35 vehicles could pass through this segment of Brunswick Road at that time. Typical traffic in this half hour is approximately 375 vehicles and

therefore employee traffic would make up less than 10% of traffic during the weekday morning shift change. During the 3:30PM weekday change approximately 8 employee vehicles would use this road segment with existing traffic of around 300 vehicles in that 15-minute period. If regular traffic were interfering with an evacuation from Banner Mountain or from the Greenhorn area via Jones Ridge Road, local authorities would implement traffic control. In such a situation, the project traffic, which is a small percentage compared to existing traffic, would also be redirected to minimize interference.

In a situation where a fire to the east of the Greenhorn area required all persons in the area to evacuate west via Greenhorn Road, the traffic from 810 parcels would be routed to the Greenhorn Road/ Brunswick Road/ E. Bennett Road intersection. This intersection is adjacent to the Brunswick Site. Regular traffic at this intersection is 1,200 vehicles per hour during the PM peak hour (see page 302 of pdf document of Appendix O to the DEIR – Intersection Turning Movement Count PM PEAK HR VOL). The number of vehicles from 810 parcels during a mandatory evacuation would be similar to routine peak hour traffic (1,200 vehicles per hour) at this intersection. If it were necessary, local authorities would implement traffic control at this intersection which would increase throughput as the all-way stop would no longer be required.

Project vehicles would not interfere with evacuation traffic because those project vehicles would be subject to the same emergency traffic controls as all other traffic. Furthermore, the project has exits on both Brunswick Road and E. Bennett Road which allows outgoing traffic to bypass this intersection. It would be highly unlikely that the mine site and Greenhorn area were subject to a mandatory evacuation order at the same time and the Greenhorn area could not use Ridge Road as an evacuation route. However, if this situation occurred the employees at the site (a maximum of 107) have access to 3 routes (northbound and southbound on Brunswick Road and westbound on E. Bennett Road). These 107 vehicles would take minimal time to exit the site and provide little to no interference with persons coming from the Greenhorn area, which are limited to the capacity of Greenhorn Road until they reach the Greenhorn Road/ Brunswick Road/ E. Bennett Road intersection.

Furthermore, if necessary, as noted in the DEIR (p. 4.13-17), in the event of an evacuation order in the vicinity of the proposed mine, such as an evacuation of residents off of Greenhorn Road, the incident command center could contact dispatch and direct them to contact the mine and request the mine operator to shut down the mine and cease all truck hauling operations. Generally, the Nevada County Regional Dispatch Center will have a 24-hour emergency contact for the mine. This information would also exist in the Emergency Action Plan for the mine, a copy of which will be provided to the Dispatch Center and County OES.

## Conclusion

The DEIR adequately evaluated the project's potential to substantially interfere with emergency evacuation of the surrounding communities. Based on the limited project traffic volumes, available evacuation routes, and standard emergency procedures, the project would not have a significant impact related to substantially interfering with emergency evacuation.

## Master Response 6 - Wildfire Impacts

### Comments

A number of comments received on the DEIR focus on the Project's potential to exacerbate wildfire in the area. However, as thoroughly analyzed in Chapter 4.13 of the DEIR, all potential wildfire impacts as a result of the Project, would be mitigated to less than significant.

### Discussion

The following section provides a summary of the extensive discussion and analysis of wildfire in Chapter 4.13 of the DEIR.

## Existing Environmental Setting

Section 4.13.2 of the DEIR describes the existing wildfire setting for the Project region. Both the Centennial and Brunswick Industrial Sites are located on lands classified as being within a Very High Fire Hazard Severity Zone. (DEIR, p. 4.13-1.) The Project sites are currently served by several fire agencies, which provide both wildland fire and structural fire response. (DEIR, p. 4.13-1.) Additionally, responsibility for wildland fire suppression for both sites is the primary responsibility of the state, given that both the Centennial and Brunswick Industrial Sites are located within State Responsibility Areas. (DEIR, pp. 4.13-1, 4.13-7, Figure 4.13-1.) Nevada County, in which the Project is located, also is home to the Grass Valley Air Attack Base and the Grass Valley Emergency Command Center, both of which are located at the Nevada County Airport in Grass Valley, and which provide emergency services related to wildfires in the region. (DEIR, p. 4.13-8.)

The Project sites vary as to their topography, although the entire Project region does not contain significant slopes (such as those in steep-walled canyons or mountainous valleys). (DEIR, p. 4.13-3.) Pursuant to the Project's baseline, the Brunswick Industrial Site includes approximately 58 acres of forest land, and the Centennial Industrial Site includes up to 10 acres of forest land. (DEIR, p. 4.13-3.) The DEIR discusses the wildfire history for the region surrounding the Project sites and notes that relatively few larger wildfires have occurred in the region over the past three years. (DEIR, pp. 4.13-3 to 4.13-4.)

The DEIR also discusses various fuel treatment efforts that have been ongoing within the Project region. (DEIR, p. 4.13-5.) Figure 4.13-2 of the DEIR depicts the completed, active, and planned fuel treatment projects within the region surrounding the Project site. (DEIR, Figure 4.13-2.) The DEIR recognizes that many of the regional fuel treatment projects are located in steep canyons or ravines, where wildfire risk is increased. (DEIR, p. 4.13-5.)

## Regulatory Context

Section 4.13-3 of the DEIR summarizes the federal, state, and local wildfire regulations applicable to the Project. (DEIR, pp. 4.13-8 to 4.13-14.) Among other things, Section 4.13-3 describes the safety standards for buildings and development that the Project must implement, as well as the applicable local wildfire goals and policies in the Nevada County General Plan, Nevada County Emergency Operations Plan, Nevada County Local Hazard Mitigation Plan, and Nevada County Community Wildfire Protection Plan. (DEIR, pp. 4.13-9 to 4.13-14.)

## Significance Thresholds

The DEIR includes standards of significance and methodology used to analyze and determine potential Project-specific impacts related to wildfire, consistent with Appendix G of the CEQA Guidelines. (DEIR, pp. 4.13-14 to 4.13-28.) For the purposes of the DEIR, a wildfire impact is considered significant if the Project would:

- Substantially impair an adopted emergency response plan or emergency evacuation plan (**Threshold WF-1**).
- Due to slope, prevailing winds, and other factors, exacerbate wildfire risks, and thereby expose project occupants to, pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire (**Threshold WF-2**).
- Require the installation or maintenance of associated infrastructure (such as roads, fuel breaks, emergency water sources, power lines or other utilities) that may exacerbate fire risk or that may result in temporary or ongoing impacts to the environment (**Threshold**

**WF-3**).

- Expose people or structures to significant risks, including downslope or downstream flooding or landslides, as a result of runoff, post-fire slope instability, or drainage changes (**Threshold WF-4**).

The DEIR demonstrates that the Project, as mitigated, would not have significant wildfire impacts. The DEIR's analysis in relation to each of these thresholds is summarized below:

### *Threshold WF-1 (Substantially Impair an Adopted Emergency Response Plan or Emergency Evacuation Plan)*

The DEIR concludes that the Project would not substantially impair an adopted response plan or emergency evacuation plan, no mitigation is required, and any related Project impacts would be less than significant. (DEIR, p. 4.13-17.)

Nevada County's primary evacuation routes consist of major interstates, highways, and principal arterials identified on the Nevada County General Plan Land Use Map. (DEIR, p. 4.13-15.) Secondary evacuation routes, which provide egress from local neighborhood and communities, consist of routes designated on the General Plan Land Use Map as minor arterial or major collector routes. (DEIR, p. 4.13-15.) Brunswick Road, which is the public road applicable to the Project, is considered a minor arterial route, and thus is considered a secondary evacuation route—not a primary evacuation route—for the County. (DEIR, p. 4.13-15.)

The Project will include the hauling of engineered fill and barren rock by trucks within the Brunswick Industrial Site using only on-site private roads, from the Brunswick Industrial Site to the Centennial Industrial Site using Brunswick Road and Whispering Pines Lane, and/or from the Brunswick Industrial Site off-site to local and regional markets using Brunswick Road to State Route 20/49. (DEIR, pp. 4.13-15 to 4.13-16.) Over the life of the Project, up to 118 haul truck round trips would occur on Brunswick Road during the hours from 6 a.m. to 10 p.m., seven days per week, which equates to approximately 7.4 haul truck round trips per hour on Brunswick Road. (DEIR, p. 4.13-16.)

In the event of a wildfire or other emergency that requires evacuation, the incident command would direct the County Office of Emergency Services to issue an evacuation order and provide related notifications to residents. (DEIR, p. 4.13-16.) If an evacuation order occurs in the vicinity of the Project, such as an evacuation of residents off of Greenhorn Road, the mine would be contacted and asked to temporarily shut down the mine and cease all truck hauling operations. (DEIR, p. 4.13-17.) Ceasing haul truck operations during the emergency evacuation order, in addition to the temporary cessation of mine operations, would ensure that the Project would not have the potential to physically interfere with an emergency evacuation plan. (DEIR, p. 4.13-17.)

Therefore, the Project would not substantially impair an adopted response plan or emergency evacuation plan, no mitigation is required, and any related Project impacts would be less than significant. (DEIR, p. 4.13-17.)

### *Threshold WF-2 (Due to Slope, Prevailing Winds, and Other Factors, Exacerbate Wildfire Risks, and Thereby Expose Project Occupants to, Pollutant Concentrations from a Wildfire or the Uncontrolled Spread of a Wildfire)*

The DEIR concludes that, with the implementation of Mitigation measure 4.13-2 (Vegetation Management Plan), the Project's potential wildlife impacts would be reduced from potentially significant to less than significant. (DEIR, p. 4.13-22.)

The Brunswick and Centennial Industrial Sites vary as to their topography, and although less than 7 acres of steep slopes (equal to or greater than 30%) occur on the Brunswick Site and approximately 4 acres of steep slopes occur on the Centennial Site, both sites do not contain any significant slopes, such as those in steep-walled canyons or mountainous valleys. (DEIR, p. 4.13-17.)

With respect to prevailing winds, the predominant wind direction at the Project site area is from the North-East and South-West directions, which suggests that a fire burning in the forest terrain southwest of the Project could burn through the Sites due to prevailing southwesterly winds. (DEIR, p. 4.13-17.)

Although the Project includes approximately 58 acres of forest land at the Brunswick Industrial Site and up to 10 acres of forest land at the Centennial Industrial Site, according to the Project's baseline, the Project proposes to remove approximately 6.5 acres of the 58 acres of forest land on the Centennial Industrial Site and 18.5 acres on the Brunswick Industrial Site. (DEIR, p. 4.13-18.) Thus, the proposed project would result in the removal of approximately 25 acres of forest land, in addition to the removal of other mid- to low-level vegetation. (DEIR, p. 4.13-18.) The DEIR concludes that a reduction in on-site vegetation would result in a concomitant reduction in fuel sources, and thus, a reduction in wildfire hazard. (DEIR, p. 4.13-18.)

Additionally, multiple ongoing and planned fuel treatment projects are located in the Project region, which would further reduce wildfire risk in the Project area. (DEIR, p. 4.13-18.)

The Project is also subject to a Fire Protection Plan (FPP), which among other things requires the implementation and maintenance of two defensible space zones around the proposed industrial buildings on the Brunswick Industrial Site, within the property boundaries, as shown in Figure 4.13-3 of the DEIR. (DEIR, p. 4.13-18.) The 30-foot Zone 1 defensible space would be paved with asphalt with the exception of two small areas adjacent to the covered conveyor and to the office and warehouse, resulting in no high fuel load areas present in Zone 1. (DEIR, p. 4.13-18.) All dead or dying vegetation would be removed from the Zone 1 area during grading and other construction activities, no dead tree or shrub branches would be present in proximity to planned buildings, no firewood piles are proposed at the Project site, and flammable vegetation or other items would be prohibited from being placed adjacent to buildings. (DEIR, p. 4.13-18.) The 100-foot Zone 2 defensible space would similarly be paved with asphalt, except for areas of existing vegetation in the perimeter of the area, and no high fuel load areas would be present in Zone 2. (DEIR, p. 4.13-20.) The Project would create horizontal and vertical spacing among shrubs and trees utilizing either or both of the Fuel Separation or Continuous Tree Canopy methods, in accordance with the State Board of Forestry and Fire Protection's applicable guidelines for defensible space. (DEIR, p. 4.13-20.) The Project site will not be allowed to exceed a maximum depth of three inches as to loose surface litter (e.g., fallen leaves or needles, twigs, bark, cones, small branches) and a maximum height of four inches as to annual grasses and forbs. (DEIR, p. 4.13-20.)

Given that the Brunswick Industrial Site is located within a Very High Fire Hazard Severity Zone, the proposed structures on the Site will comply with all applicable fire safety standards in Chapter 7A of the California Building Code, including but not limited to using ignition-resistant materials, fire-intrusion design of roofing and vents, and glazed exterior windows and doors, as well as complying with all fire code requirements set forth by the California Building Code and the California Fire Code, as determined by the County Fire Marshal at the building permit stage. (DEIR, p. 4.13-20.)

The Project will also include the installation of a fire flow system that would connect to the 18-inch Nevada Irrigation District water main in Brunswick Road, which would be reviewed by the County Fire Marshal to ensure that the fire flow system meets California Fire Code requirements. (DEIR, p. 4.13-20.)

Any use of explosives in connection with the Project would comply with applicable federal and state laws at all times, to help ensure that a significant hazard to the public or the environment through routine transport, storage, or use of explosives would not occur. (DEIR, p. 4.13-21.) Moreover, the storage and use of explosives would only occur underground at the Brunswick Industrial Site, and thus an unexpected explosive event would not be likely to exacerbate any above-ground wildfire risks. (DEIR, p. 4.13-21.)

The DEIR addresses public comments made during the Notice of Preparation review period concerning potential wildfire risks associated with the dewatering of the mine. (DEIR, p. 4.13-21.) Commenters suggested that the reduction of groundwater levels and associated drying of surface vegetation would exacerbate wildfire risk. (DEIR, p. 4.13-21.) However, the existing groundwater surface in the areas away from the creeks is below the typical depth of rooted vegetation and tap roots from trees, especially during the drier months. (DEIR, p. 4.13-21; please also see Master Response 33 – Groundwater Dependent Vegetation.) Further discharge of treated water to South Fork Wolf Creek would prevent the lowering of groundwater levels along the creek because the full dewatering volume would be discharged, whereas only a small fraction of the groundwater would come from the creek area. (DEIR, p. 4.13-21.) The potential increased recharge due to the enhanced base flow in South Fork Wolf Creek would more than offset any effects from dewatering in the area near the creek. (DEIR, p. 4.13-21.) The DEIR therefore concludes that the dewatering of the mine would not affect the available moisture for vegetation in the Project area and would not increase fire risk due to reduced groundwater levels. (DEIR, p. 4.13-21.)

Overall, with respect to this threshold, the DEIR concludes as follows:

> The Centennial and Brunswick Industrial Sites have limited steeply-sloping topography that is known to exacerbate wildfire risk and spread. Prevailing wind conditions within the surrounding area are from the North-East and South-West directions, both of which have forest lands. The incorporation of defensible space around proposed structures at the Brunswick Industrial Site, as well as designing buildings in conformance with Chapter 7A of the CBC, would help to slow the spread of wildfire moving through the area. In addition, proposed improvements at both Sites would reduce the vegetation fuel load in the area. Nevertheless, vegetation would remain on both Sites and would need to be managed on an ongoing basis. In addition, use of hydrocarbon-powered heavy-equipment on-site could exacerbate wildfire risk. Without implementation of a vegetation management plan, the proposed project could have a significant impact related to exacerbating wildfire risks, and thereby exposing project occupants to, pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire. (DEIR, p. 4-13.22.)

Therefore, to mitigate against any significant wildfire impacts, the Project will be required to implement a comprehensive Vegetation Management Plan for both the Brunswick and Centennial Industrial Sites, for the duration of the Project. (DEIR, p. 4.13-20, Mitigation Measure 4.13-2 [DEIR, pp. 4.13-22 to 4.13-23].) Local fire agencies, including CAL FIRE, have concluded that ongoing implement of the Vegetation Management Plan would reduce wildfire risks to the Project to a less-than-significant level. (DEIR, p. 4.13-20.)

The result of implementing Mitigation Measure 4.13-2 (Vegetation Management Plan) is the reduction of the Project's potential wildfire impacts from potentially significant to less than significant. (DEIR, p. 4.13-22.)

### *Threshold WF-3 (Require Installation or Maintenance of Associated Infrastructure That May Exacerbate Fire Risk or Result in Temporary or Ongoing Environmental Impacts)*

Although the proposed project would include installation of various infrastructure components, none of the improvements would be expected to exacerbate wildfire risk or otherwise result in significant environmental impacts. (DEIR, pp. 4.13-24 to 4.13-25.) In analyzing this significance threshold, the DEIR acknowledges that certain improvements generally may have the potential to exacerbate wildfire risk under certain conditions, such as the extension of the overheard power line along Brunswick Road if the line comes in contact with tree limbs or overhanging vegetation, or the installation of two, 12,000-gallon above-ground diesel fuel storage tanks on the Brunswick Industrial Site. (DEIR, p. 4.13-24.) However, given that the installation of these improvements would comply with all applicable laws and regulations, and taking into account the location of the storage tanks (e.g., the storage tanks at the Brunswick Industrial Site will be located in the industrial building complex, away from existing and proposed vegetation), the improvements would not be expected to exacerbate wildfire risks or result in significant environmental impacts. (DEIR, p. 4.13-24.)

Therefore, no mitigation is required as to this threshold, and any related Project impacts would be less than significant. (DEIR, p. 4.13-25.)

### *Threshold WF-4 (Expose People or Structures to Significant Risks, Including Downslope or Downstream Flooding or Landslides, as a Result of Runoff, Post-Fire Slope Instability, or Drainage Changes)*

In evaluating this threshold, the DEIR analyzed data from the 2017 McCourtney Fire, which occurred approximately 3.5 miles south/southwest of the Project area and burned approximately 76 acres. (DEIR, pp. 4.13-25 to 4.13-26.) The post-fire debris-flow assessment performed by the U.S. Geological Service concluded that the potential for debris flow occurrence within on-site drainages is low, at 0-20 percent. (DEIR, p. 4.13-26.) The topography and vegetation of the region affected by the McCourtney Fire are generally similar to the Project region, and the DEIR reasonably concludes that one can apply these conclusions to the Brunswick and Centennial Industrial Sites given that they similarly lack substantial steep topography and include mildly incised drainages. (DEIR, p. 4.13-26.) Moreover, although the engineered fill pads would constitute the largest slopes on the Project sites, the proposed slopes would be relatively gradual at 3:1 (H:V), the fill material would comprise a flexible composite range of blast rock and sand tailings produced underground, and the inclusion of silt into the materials would provide additional cohesion and increase the friction angle of the fill. (DEIR, p. 4.13-26.) The Project also would include drainage facilities to capture runoff prior to entering the creeks, thus minimizing flooding potential downstream. (DEIR, p. 4.13-26.)

Therefore, the probability for post-fire debris flows at the Project Sites is low, no mitigation is required as to this threshold, and any related Project impacts would be less than significant. (DEIR, p. 4-13.26.)

### Conclusion

As demonstrated in the DEIR, all potential wildfire impacts for the Project, as mitigated, would be less than significant and the Project will not substantially impact any adopted emergency response plan or emergency evacuation plan.

## Master Response 7 - Location of Future Mining Areas

### Comments

Several commenters state that the DEIR does not evaluate the project's proposed underground mining operations within the entire mineral rights area, and thus, the DEIR is inadequate. Common concerns related to this general assertion is that the DEIR's groundwater modelling is inadequate and the extent of vibrations associated with underground mining is underestimated

### Discussion

Economic gold mineralization does not exist everywhere within the applicant's mineral rights area at 500 feet below surface, and is only in discrete areas; thus, mining would not occur everywhere within the mineral rights area. As such, analysis of mining the entire mineral rights area is not supported by the known geology and is speculative.

#### DEIR Adequately Evaluates Potential Groundwater Effects from Underground Mining

New underground mining excavations, used for the analysis of groundwater impacts, is based upon information provided by the applicant, as shown on Figures 5-1 of Appendix K.3 and Sheet 15 of Appendix K.2. As shown in these figures, assumed mining areas are based on the projected down-dip extensions to mineralized veins historically mined. The mining depths analyzed in the groundwater model were based on the applicant's intended mining plan, which is focused on the areas where gold mineralization was actually encountered, at depths deeper than 1,000 feet below the surface.

Itasca analyzed the impacts of variations in the location of future mine workings. Sensitivity Scenario 6 considered the significant expansion of mining in areas with potential for mineralization, as shown in Figure 5.10 of Appendix K.3. As shown in Figure 5-12, the major mining expansion studies in Scenario 6 did not result in a significant expansion in the simulated 5-foot drawdown contour versus the base case. As stated on page 31 of Appendix K.3, it is expected that the actual mining areas will change from the modeled mining areas due to vein geometry and discoveries, which will only be known after extensive underground exploration is completed in the future. Itasca recommends that the groundwater flow model be updated periodically after dewatering commences. Updated modeling would incorporate changes to the long-term mining plan, data from monitoring wells, and measured pumping rates. The DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the Project could result in a significant impact to groundwater supplies.

Nonetheless, to address public concerns regarding the scope of future mining within the mineral rights area, the applicant has agreed to an enforceable condition of approval that will limit the area of permitted underground mining to a smaller area within the mineral rights area (shown on maps A101, A201 and A202), and will also prohibit blasting closer than 500 feet below ground

surface except for construction of the service shaft. The condition of approval language is provided below:

> *Except for the construction of the proposed Service Shaft, all underground blasting for production, tunnelling, and raising would take place more than 500 feet below ground surface and no underground mining will take place outside of the area denoted on the maps included in Appendix A of the Final EIR.*

A Groundwater Monitoring Plan (GMP) is required for the Project under Mitigation Measure 4.8-2(a). Ongoing groundwater monitoring would be required, and groundwater-level information shall be obtained from the project groundwater monitoring wells and collected on a quarterly basis and submitted in report form to the Nevada County. Mitigation Measure 4.8-2(b) requires that if it is determined based on the GMP that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified. As stated in Mitigation Measure 4.8-2(a), groundwater monitoring is required on an ongoing basis. Therefore, changes in locations of mine workings, and the effect on groundwater levels at surface, would be observed by the GMP and replacement water would be required. The GMP is designed to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented.

## DEIR Adequately Evaluates Potential Blasting Vibration and Noise from Underground Mining

Blasting vibration are analyzed in Section 4.10 of the DEIR. As discussed in the DEIR and in Appendix M, except for the construction of the proposed Service Shaft, all underground blasting for production, tunnelling, and raising would take place more than 500 feet below ground surface. A condition of approval for this blasting depth restriction has been included in the Final EIR, as discussed above. As discussed in section 4.10-4 of the DEIR and the PBS Technical Report, a maximum of 0.23 inches per second vibration is modelled where a longhole blast could occur directly beneath a receptor at 500 feet depth. Notwithstanding the rarity of this situation, such a blast might occur every three or four days between shift changes (7AM and 7PM) and would last for only seconds. At 500 feet depth and a horizontal offset of 1400 feet, such a longhole blast would be undetectable by blasting seismograph (PPV <0.05 in/sec). Regular drift round blasting, occurring approximately twice daily over several seconds, is modelled to result in a maximum of 0.14 inches per second vibration at a depth of 500 feet directly beneath a receptor. At 500 feet depth and a horizontal offset of 900 feet, a drift round blast would be undetectable by blasting seismograph (PPV <0.05 in/sec). Historic mining was completed to approximately 1600 feet depth and the majority of future mining is expected to be below the historic mine surface area. At this distance, regular drift round blasting and longhole blasts would be undetectable by blasting seismograph (PPV <0.05 in/sec) at receptor locations directly above the blast location. Several commenters have expressed concern about noise from blasting and the effect of this noise based on the location of mining underground. As opposed to vibration, audible noise from underground blasting can only propagate to surface from through the mine tunnels and shafts. Therefore, noise impacts from blasting are relative to a receptor's proximity to the shaft headframes at the Brunswick Site and not the location of the underground workings. As stated on page 4.10-44 of the DEIR, the noise from blasting is less than significant even for the closest receptors to the Brunswick shaft headframe.

### Conclusion

The DEIR (Chapters 4.8 and 4.10) adequately evaluates the potential environmental effects that could result from the project's reasonably anticipated underground mining operations, including effects to groundwater and noise and vibration, and concludes that impacts would be less-than-significant with implementation of mitigation. Nonetheless, to address public concerns regarding the scope of future mining within the mineral rights area, the applicant has agreed to an enforceable condition of approval that will limit the area of permitted underground mining to a smaller area within the mineral rights area, as shown on maps A101, A201 and A202 in Appendix A to this Final EIR, and will also prohibit blasting closer than 500 feet below ground surface except for construction of the service shaft.

## Master Response 8 - Mine Waste Characterization

### Comments

The County received several comments asserting that the waste characterization conducted on samples from the Project site is inadequate and that further testing should be done before the project is approved, in an effort to ensure water quality impacts do not ensue from stormwater runoff at engineered fill sites.

### Discussion

As discussed below, geochemical testing was already conducted on samples from the Project site to assess impacts to water quality. Moreover, the DEIR requires that a report of waste discharge (RoWD) be submitted to the Central Valley Regional Water Quality Control Board (CVRWQCB), and approval of Waste Discharge Requirements (WDRs) prior to placement of any mine waste. Significant additional testing of rock material will be required as part of the process of obtaining WDRs from the CVRWQCB. Given the geochemical testing that has already been conducted to characterize the water quality impacts of engineered fill and cemented paste backfill placement, and the further waste characterization that will be required as part of the WDRs approval process, additional testing is not required for the purposes of CEQA.

Section 4.8.4 of the DEIR provides an analysis of the environmental impact from mine wastes produced by the proposed Idaho-Maryland Mine Project. The impact to water quality from mine waste is considered potentially significant for the purposes of the DEIR's analysis, and mitigation is necessary to reduce the impact to less than significant. (see DEIR, Impact 4.8-1; Mitigation Measures 4.8-1(a) to 4.8-1(e).) These mitigation measures (4.8-1(a) to 4.8-1(e)) require the applicant to submit a RoWD and receive an approved Waste Discharge Requirement (WDR) from the CVRWQCB prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)).

The Project would be subject to California mining waste regulations as discussed on pages 4.8-28 and 4.8-29 of the DEIR. Barren rock, sand tailings, and cemented paste backfill will be considered mining waste under California Water Code Section 13050(q)(1) and Title 27 of the California Code of Regulations (CCR), Sections 22470 et seq. and therefore subject to regulation and oversight by the CVRWQCB prior to placement of mine waste.

Section 4.4 of Appendix K.2 of the DEIR provides geochemical testwork conducted on tailings and barren rock samples from the project. Testwork included Acid Based Accounting (ABA), Total Metals, and California Waste Extraction Testing (WET). The Waste Extraction Test (WET) should be used to determine the amount of extractable substance in waste rock (CCR Title 22 Division 4.5, Chapter 11, Article 5, Appendix II). The overall purpose of the barren rock and tailings sampling and laboratory analysis was to identify the general characteristics of that specific

material type. As such, the results of the barren rock and tailings testing provide reliable and representative results for consideration in the DEIR and for assessment of the potential effects of the use of that material for engineered fill and cemented paste backfill.

The analysis and testwork used in the preparation of the DEIR is for the purposes of analyzing the water quality impacts of the project consistent with the California Environmental Quality Act (CEQA) but is not intended to be a RoWD. Further testing of material will be required prior to submittal of a RoWD; however, a RoWD is not required at this stage of the project. Some commenters requested that additional testwork be completed as part of the CEQA analysis similar to what will be required for the RoWD; however, the testwork already completed is sufficient to assess project impacts, and engineering level detail is not required in an EIR. (*Dry Creek Citizens Coalition v. County of Tulare* (1999) 70 Cal.App.4th 20, 26.) Based on the results of the testwork, the DEIR concludes that the effect of the proposed actions on water quality would be potentially significant. The mitigation measures, as confirmed in the April 4, 2022 comment letter from the Central Valley Water Board, identify the steps that must be taken to reduce the potential impacts to less than significant. The engineering details and intensive sampling described by many commenters would be developed and completed through the implementation of mitigation measures, and is not required to be completed as part of the CEQA process. The final determination of classification is done when the RoWD is submitted and an approved WDR is received from the CVRWQCB as required in Mitigation Measures 4.8-1(d) and 4.8-1(e). The RoWD would be prepared and submitted in compliance with CCR Title 27 Sections, 21710-21760. (CCR Title 27 Section 22470(a)). The WDR will incorporate the necessary construction, monitoring, and closure of the waste management unit, based on the waste characterization, in order to protect water quality.

As described in Section 3.7 of the DEIR, underground exploration would take place after mine dewatering is complete and throughout the life of the mine. Exploration would be done primarily with diamond core drilling throughout the mine area. Exploration would produce core samples that would be brought to the surface for analysis to determine future mining areas. Metallurgical testing would be conducted to create representative tailings samples and cemented paste backfill sample for WET testing.

The CVRWQCB requires that the sample material used for a waste characterization is representative of the entire range of mining waste discharged. Therefore, consistent with CVRWQCB requirements, a sampling plan that addresses representative sampling of the mining waste would be submitted to the CVRWQCB prior to sampling and the CVRWQCB will be notified when the samples are to be collected so that they may observe the process. (see CVRWQCB website Submitting a Report of Waste Discharge – CVRWQCB 2022). Collection of field samples and subsequent testing of the expected mining waste would be based on clearly defined objectives identified in a sampling plan, approved by the CVRWQCB, prepared by professional(s) registered to practice in California in the field of engineering or geological sciences (see appropriate professional CCR Title 27 Section 21710 (d).

Waste characterization testing that will be used in a RoWD must be performed by California certified labs. A California certified lab is a lab accredited by the California Environmental Laboratory Accreditation Program. (see CVRWQCB website Submitting a Report of Waste Discharge – CVRWQCB 2022). The WET would be used to determine the amount of extractable substances in waste rock and Acid Generation Potential testing must also be performed to determine whether the material has the potential to generate acid (see Tech Note Mining Waste Characterizations - CVRWQCB 2008).). Further analysis may be required using kinetic testing, which would help determine the mining waste potential for long term acid generation (see Tech

Note Mining Waste Characterizations - CVRWQCB 2008). The waste characterization would be done to the satisfaction of the CVRWQCB to allow them to approve the WDR.

Mining Waste is classified in accordance with CCR Title 27 Section 22480(b) as Group A, Group B, or Group C mining wastes based on an assessment of the potential risk of water quality degradation posed by each waste.

**Group A**

- Mining wastes of Group A are wastes that must be managed as hazardous waste pursuant to Chapter 11 of Division 4.5, of Title 22 of this code, provided the CVRWQCB finds that such mining wastes pose a significant threat to water quality.

**Group B**

- Mining wastes that consist of or contain hazardous wastes, that qualify for a variance under Chapter 11 of Division 4.5, of Title 22 of this code, provided that the CVRWQCB finds that such mining wastes pose a low risk to water quality; or
- Mining wastes that consist of or contain nonhazardous soluble pollutants of concentrations which exceed water quality objectives for, or could cause, degradation of waters of the state.

**Group C**

- Mining wastes from Group C are wastes from which any discharge would be in compliance with the applicable water quality control plan, including water quality objectives other than turbidity.

The testwork conducted in connection with preparation of the DEIR demonstrates that the engineered fill and cement paste backfill will likely be considered Group C mining waste. However, the waste characterization conducted as part of the RoWD for the project will provide the basis for which features, operation plans for waste containment, precipitation and drainage controls, are required for the project in accordance with CCR Title 27 Section 22490. As part of the WDRs, the mine operator will also be required to conduct water quality monitoring in accordance with CCR Title 27 Section 22500 and closure and post closure maintenance plans in accordance with CCR Title 27 Section 22510.

## CVRWQCB Permitting over 80-Year Use Permit Term

Several comments have been received on ongoing waste characterization requirements throughout the 80-year term of the Use Permit. In accordance with CCR Title 27 Section 21710(a)(4), once WDRs for a mining waste unit have been issued, the CVRWQCB must be notified of any material change in the types, quantities, or concentration of mining wastes discharged within a reasonable time before those changes are made effective. Therefore, as exploration and mine planning continue throughout the life of the mining operation any changed or updated information would be provided to the CVRWQCB and in some cases incorporated into the WDRs.

As discussed in Master Response 11 – Location of Future Mining Areas, the RoWD must also include a report on the physical and chemical characteristics of the waste, in compliance with Water Code section 13260(k), that could affect its potential to cause pollution or contamination as well as a report that evaluates the potential of the discharge of mining waste to produce, over the long term, acid mine drainage, the discharge or leaching of heavy metals, or the release of other hazardous substances. The WDR's will require continuous and routine characterization and

classification (Cal Code regs Title 27 section 22480(b)) of the mining waste to evaluate any possible changes in the geological or geochemical nature of the waste. The applicant will prepare and implement a Waste Characterization Plan (Characterization Plan) which will be incorporated into the approved WDR. The purpose of the Characterization Plan is to continually evaluate the different forms of mining wastes and to appropriately classify these wastes as Group A, Group B, or Group C based on an assessment of the potential risk of water quality degradation posed by each waste. Through the WDR these wastes will be required to be managed, treated, stored, or disposed of in a manner that is protective of water quality. The applicant shall not sell or utilize waste rock and tailings from the Project for construction aggregate or fill purposes offsite (i.e. sites other than the applicants Brunswick and Centennial sites) unless such material has been tested and confirmed to qualify as Group C mining waste under California Code of Regulations Section 22480 and the approved WDR. The specific methods, volumes and frequency of characterization will be established in the approved WDR. Mitigation Measure 4.8-1(e) has been revised in this Final EIR to more clearly reflect the above ongoing waste characterization requirements (please see Master Response 11 for more detail).

Finally, in accordance with CCR Title 27 Section 21720 (f), the discharger is required to maintain records of the volume and type of each waste discharged at each unit and the manner and location of the discharge. These records shall be available until the waste unit is closed and available for review by the CVRWQCB. Therefore, as mining waste is produced it would require continuous inventory and testing in accordance with the approved WDR. In accordance with CCR Title 27 Section 21720 (c), Unit classifications and WDRs for existing Units would be fully reviewed in accordance with schedules established by the CVRWQCB and specified in the WDR.

### Conclusion

California Waste Extraction (WET) testing was performed on samples of mine materials and the results of these tests suggest the engineered fill (barren rock and sand tailings) will be a Group C mining waste. Nonetheless, the DEIR has concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measures 4.8-1(d) and 4.8-1(e) to address these potential impacts and reduce the impact to less than significant. The purpose of the Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board is to ensure the effluent from mine waste does not impact water quality. Further testing will be required as part of the RoWD and WDR process as required by Mitigation Measures 4.8-1(d) and 4.8-1(e) such that any impacts will be mitigated. WDRs for the Project will require ongoing waste characterization, monitoring, and reporting to ensure compliance.

## Master Response 9 - Historical Mine Waste at Centennial Site

### Comments

Several commenters asserted that the chemical characteristics of the historic mine waste on the Centennial site that is being cleaned up as a separate project under the jurisdiction of DTSC, is

evidence that the waste rock from the Project will lead to water quality impacts and impacts to human health. Several commenters have also incorrectly asserted that the Centennial Site is either designated or under consideration to be listed as a "Superfund" site under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) by the USEPA.

## Discussion

The Centennial Industrial Site was the location used for the storage of mine tailings by the historical mining operation. Detailed evaluations of these historical mine wastes are provided in the Preliminary Endangerment Assessment (PEA) and Draft Final Remedial Action Plan (RAP) for the Centennial M-1 Property. These reports were prepared pursuant to a Voluntary Cleanup Agreement (VCA) between Rise Grass Valley Inc. and the California Environmental Protection Agency Department of Toxics Substances Control (DTSC). These reports have been reviewed by and have received technical approval from the DTSC. The VCA project is a separate project from the Idaho-Maryland Mine Project. See Master Response 4, Cleanup Project is a Separate Project Under CEQA.

### Elevated Metals in Historical Mine Waste

Elevated metal concentrations are present in certain areas of the historical mine waste, and these portions of the mine waste are to be consolidated and capped to reduce the potential for future routine contact and human health risk. The plan and objectives presented in the RAP are to excavate, consolidate, and cover these materials to eliminate these potential health risks. Figure 5, which is reproduced from the RAP, shows the areas (hatched in yellow) where the cleanup of materials with elevated metals is proposed. The historic rock dam contains the majority of the materials where elevated metals are present in historic mine waste. These excavation areas (ETP-E and WTP-N), total 118,000 cubic yards or 86% of the 138,000 cubic yards of material proposed to be remediated in the RAP and 26% of the total 534,000 yards of historical mine waste present in assessment areas of the site. Figure 6 shows a labeled historic aerial photograph of the tailings facility which is reproduced from the RAP. A rock berm was built (label 8) across the northern side of the property by the historical operator in order to contain the tailings produced by mineral processing. The construction of this rock berm commenced in 1920 and was constructed from waste rock produced from the underground mine before 1920. The operations report for 1920 discusses this and states "Tailings Impounding Dam: The waste rock from the mine is being utilized for the construction of this dam, the cost of which is nominal for the reason that the waste dump proper is now large, requiring long tracks and is constantly decreasing in height as the rill rises rapidly in the direction in which the dump is being extended. The dam completed will impound 1,400,000 cubic yards of tailings. The proposed dam, etc. has been submitted to the Debris Commission and accepted by them as satisfactory." (IMMC 1921)

During the historic era of mining virtually all exploration was done by tunneling in mineralized veins in order to locate ore shoots with economic gold values. Therefore, the waste rock produced in this era of mining, and used in the construction of the tailing's berm, is composed of mineralized material with low gold values but elevated metals due to the presence of sulfides (such as pyrite). Sheet 9 of Appendix K.2 of the DEIR shows the shallow historical mine workings and illustrates how almost all tunnelling was conducted in mineralized veins. As described in Section 3.7 of the DEIR, the proposed development tunnels, which will be used to provide access to gold-bearing veins, will be constructed in non-mineralized rock (barren rock) outside of mineralized zones. Gold mineralization would be located and delineated by exploration core drilling. Therefore, the great majority of waste rock produced by the proposed Idaho-Maryland Mine Project will be unmineralized barren rock rather than the mineralized waste rock produced by the historical mine.

Approximately 37.1 acres of the 56.4-acre Centennial Site are occupied by former tailings ponds, which are separated into two primary assessment areas: Eastern Tailings Pond (ETP) and Western Tailings Pond (WTP). The ETP is located closer to the historical off-site gold ore processing facility and was reportedly constructed first, during the early days of the mining operation when the mercury amalgamation process was used to recover gold. The WTP was reportedly constructed later, when the cyanide recovery process was used to recover gold (NV5 2021).

The majority of the historical mine tailings do not contain significantly elevated metals except for certain hot spots in the western and eastern tailing ponds. These excavation areas (Hot Spots), total 15,800 cubic yards or 11% of the 138,000 cubic yards of material proposed to be remediated in the RAP, 6% of the 263,000 yards of tailings contained in the western (WTP) and eastern tailings (ETP) pond assessment area, and 3% of the total 534,000 yards of historical mine waste present in assessment areas of the site. Figure 5 (included in this master response below), which is reproduced from the RAP, shows the hot spot locations (circles hatched in yellow) where the cleanup of tailings materials with elevated metals is proposed in the separate DTSC project.

One small area, TP19 Hot Spot, was proposed to be treated and neutralized by the addition of cement. The volume of TP19 was estimated at 4,200 cubic yards which is less than 1% of the total 534,000 yards of historical mine waste present in the assessment areas at the site (NV5 2021). CVRWQCB staff concurs with the proposed treatment of the TP19 Hot Spot material (CVRWQCB 2021).

The Western Tailings Pond (WTP) contains the sand tailings derived primarily from processing by ball milling and flotation processing, from 1936 to 1956. Table 2b of the RAP shows total metals concentrations from samples taken at the Centennial Site sorted by area. As shown in Table 2b of the RAP, despite the inclusion of sulfide minerals that would not be present with the proposed processing method, metal values from 41 samples of the historical tailings in the WTP are low. For example, arsenic values range from 1.8 to 28 ppm and average approximately 7 ppm.

During the CEQA process for the RAP, NV5 submitted 19 samples retained from the PEA sampling program to EMSL Analytical Inc. in San Leandro California for CARB 435 (Polarized Light Microscopy) PLM asbestos testing. These samples are distributed across the Centennial Site and represent approximately 37 acres or 2 acres per sample. All 19 samples were <0.25% asbestos by PLM. NV5 submitted 10 samples retained from the PEA sampling program to EMSL for TEM asbestos testing using method EPA 600/R-93/116. No asbestos structures were present in 7 samples from the western tailings area. Three samples from the eastern tailings area had detectable asbestos ranging from 8.1 x10^7 to 2.1 x10^8 structures per gram and <0.01% to 0.02% asbestos by weight.

## Centennial Site is Not a Superfund Site

The Centennial Site has never been on the National Priorities List[1] (A "Superfund site"). The Centennial Site has never been proposed to be placed on the National Priorities List (NPL). The USEPA has prepared a Site Inspection Report in 2019 for the Centennial site but did not score the site using the Hazard Ranking System (HRS). The HRS is the primary method used to place sites on the NPL, and sites receiving a HRS site score of 28.50 or greater are eligible for placement on the NPL[2]. Even if the USEPA later decided to score the Centennial Site using the HRS, the site would not likely meet the criteria for placement on the NPL, as discussed below.

[1] https://www.epa.gov/superfund/superfund-national-priorities-list-npl
[2] https://www.epa.gov/superfund/about-superfund-cleanup-process#pasi

The HRS uses a structured analysis approach to scoring sites that assigns numerical values to factors that relate to risk based on conditions at the site. The factors are grouped into three categories: (1) likelihood that a site has released or has the potential to release hazardous substances into the environment; (2) characteristics of the waste (e.g., toxicity and waste quantity); and (3) people or sensitive environments (targets) affected by the release. In this case, the Centennial Site would not score highly on the HRS because: as to factor one, it has a limited likelihood of releasing hazardous substances into the environment given that the material has been in place for many decades; as to factor two, the waste at issue (arsenic) is naturally occurring in the region, and is not of a particularly high quantity or toxicity given its concentration; and as to factor three, the site is not used by people and is not a sensitive environment. As such, the Centennial Site is unlikely to be considered eligible for inclusion on the NPL. Moreover, the Centennial Site would need to be scored using the HRS and then go through subsequent processes before being selected for listing on the NPL. Given that the USEPA has not chosen to score the site using the HRS, it can be reasonably inferred that the USEPA also has concluded that the site would not likely score high enough to be placed on the NPL.

## Project is Different than Historical Mining

Early mineral processing at the historical mine solely used stamp mills and mercury amalgamation to recover gold, and all tailings were placed into the Eastern Tailings Pond. In the mid 1930's a new processing plant was constructed which utilized a ball mill for grinding and flotation plant. The tailings produced from flotation were pumped to the tailings pond and sulfide concentrates produced by flotation were leached with cyanide to produce gold dore (bricks) with the residual material (sulfide concentrate) pumped to the tailings pond (Clark 2005). These historical (and less efficient) processing methods are believed to be the primary source of the hot spots in the tailings ponds. As described in Section 3.7 of the DEIR, mineral processing for the proposed Idaho-Maryland Mine Project uses a flotation plant to remove the majority of sulfide minerals which would be recovered in the sulfide mineral concentrate for shipment off-site. The Project does not use mercury or cyanide in gold processing. As disclosed in Appendix K.2 of the DEIR, sulfide sulfur recoveries to the flotation concentrate during testwork ranged from 92.9% to 96.3%.

The historical mine waste at the Centennial Site was derived from production from the period from 1920 -1956 and therefore is representative of a substantial portion of the historical mine's production. Unlike historical mining, the proposed Idaho-Maryland Mine Project would not produce large quantities of mineralized waste rock and would remove most sulfide minerals from the sand tailings before the sand tailings are placed as engineered fill. The proposed project is intended to produce mine waste with lower sulfide and metal content than those produced historically.

Given that the proposed future mine waste will by nature and by process design be less mineralized than the historical mine waste, the future mine waste will likely also be classified as Group C waste. Regardless of the future waste classification, the future placement of mine waste as engineered fill will be subject to regulation under the California Code of Regulations (CCR) Title 27, which sets forth requirements pertaining to the discharge of mine waste to land and requires the development of Waste Discharge Requirements (WDRs) by the CVRWQCB.

Prior to development of WDRs and placement of future mine waste as engineered fill, and pursuant to CCR Title 27 and the California Water Code, the CVRWQCB will require:

- A report on the physical and chemical characteristics of the waste and its potential to cause pollution or contamination;
- A report that evaluates the potential for acid mine drainage, discharge or leaching of

heavy metals or the release of other hazardous substances; and
- A detailed plan and management strategy for the placement of mine waste as engineered fill that prevents the pollution or contamination of the waters of the state.

The WDRs will include requirements for routine sampling and analysis of mine waste during operation of the mine to verify the mine waste characteristics and classification under CCR Title 27. Please refer to Master Response 8 – Mine Waste Characterization, for further discussion.

Furthermore, the DTSC will require that mine waste placed at the site be protective of human health by meeting the cleanup goals established in the RAP for the historical mine waste.

## Conclusion

This master response demonstrates that the proposed project can be distinguished from historical mining in manner of process methods (e.g., no use of mercury or cyanide) and tunnelling methods (e.g., tunneling in barren rock as opposed to historical tunneling in mineralized veins with elevated metals), which supports the DEIR's conclusion that the project's potential water quality impacts (i.e., App. G X(a)) from generation and deposition of waste rock would be less-than-significant with implementation of mitigation measures.

## Master Response 10 - Explosives, Reagents, and Brunswick Fill

### Comments

Several commenters have expressed public hazard concerns related to routine explosives transport, water quality effects from reagents proposed to be used for mineral processing, and human health and water quality effects from historic mine waste at the Brunswick Site.

### Discussion

#### Explosives

Several commenters asserts that the specific frequency of explosives deliveries and/or the Level of Service of intersections from the traffic analysis should be used in the DEIR to analyze the impact of explosives transport. As stated in the DEIR, explosives deliveries would take place from 1 to 3 weeks. (DEIR, p. 4-7.24.) The average of 2 weeks (15 days as calculated by the commenter) is implied from this range. As discussed on pages 14 and 15 of Appendix M of the DEIR, tunneling (drift) blasts would take place daily but production longhole blasting would take

place once every 3-4 days. At certain times explosives may be consumed immediately upon delivery underground when loading larger production longhole blasts. Therefore, explosives consumption is not uniform over every day. The Level of Service is a qualitative description of traffic flow from a vehicle driver's perspective based on factors such as speed, travel time, delay, and freedom to maneuver. As discussed in Section 4.7 of the DEIR, the transportation of explosives in the United States is highly regulated and has an excellent safety record. The analysis of explosives transport in Section 4.7 of the DEIR does not depend on the frequency of explosives delivery or the Level of Service to determine the significance of hazards. Therefore, an increase in delivery frequency or an intersection's level of service would not materially affect the DEIR's conclusion that a less than significant impact would result from explosives transport, storage, and use, after implementation of mitigation. As stated on page 4.7-24 of the DEIR, hauling of explosives would occur using Brunswick Road to State Routes (SR) 20/49. Explosives would be transported directly to the Brunswick Site by licensed explosive suppliers that possess the requisite permits, including a CHP hazardous materials transportation license and U.S. DOT hazardous materials permits. State Routes 20 and 49 are designated as explosive transport routes by the CHP[3]. Additionally, the explosives supplier would be required to have a sufficient insurance policy. Table 4.7-2 of the DEIR provides regulations for the transport of explosives. As shown in the table, insurance is regulated by 49 CFR 387. As per this regulation the minimum limit of insurance for freight vehicles of 10,001 pounds or greater transporting explosives is $5,000,000.

Therefore, the DEIR correctly concludes that the project's transport of explosives would have a less-than-significant impact after mitigation related to creating a significant hazard to the public or the environment.

## Mineral Processing Reagents

The DEIR describes the proposed mineral processing reagents and their properties, including potential water quality effects (e.g., toxicity to aquatic organisms). Mineral processing reagent type and quantities are shown on page 297 of Appendix E.1. Subsequent to the release of the DEIR the proponent determined, based on additional metallurgical testwork, to eliminate Aeroflot 208 from the proposed reagents.

| **Reagent Type** | **Quantity Used** | | **Product** |
|---|---|---|---|
| Promoter | 200 | pounds per day | Aerophine 3418A |
| Frother | 80 | pounds per day | MIBC |
| Flocculant | 80 | pounds per day | Magnfloc 10 |

As stated on page 4.7-29 of the DEIR, the mineral processing reagents are added to the processing water and are soluble. The flotation promoter (Aerophine 3418A) attaches to the mineral particles and therefore the majority of the reagent is within the mineral concentrate, which is shipped offsite. There may be trace amounts of promoter and on the sand tailings and within moisture remaining in sand tailings. The frother (MIBC) will have a tendency to remain in water and therefore would remain in process water, which is recycled in the processing plant and not discharged to the environment. Some frother may be present in moisture remaining in sand

[3] See Map 6 of California Highway Patrol, *HPH 84.3 Explosive Material Shipments: Routes, Safe Stopping Places, and Safe Parking Places*. May 2021.

tailings after dewatering. Flocculant (Magnafloc) used for dewatering of sand tailings would generally remain in the sand tailings. Aerophine 3418 promoter is a unique, phosphine-based collector, which has no odor, is biodegradable and is not harmful to fish, aquatic invertebrates or plants. MIBC (methyl isobutyl carbinol) is unlikely to persist in the environment. The compound is readily biodegradable and completely removed from water and soil environments. MISC is practically nontoxic to fish and other aquatic organisms on an acute basis. The MSDS for Aerophine 3418A and MIBC have been attached to the Final EIR as Appendix B. As stated on page 4.7-29 of the DEIR, Magnafloc is not expected to bioaccumulate in organisms, its chemical family (polyacrylamide) is relatively non-toxic, and it is not readily biodegradable into more environmentally problematic chemicals. The mineral process plant is a closed system and no process water would be in the mine water discharge from the site. As discussed above, any residue of these reagents remaining in sand tailings do not present a risk to the terrestrial and aquatic environments. Any monitoring requirements by the Central Valley Regional Water Quality Control Board for flotation reagents would be determined in the Waste Discharge Requirement process (see Master Response 8 – Mine Waste Characterization).

As demonstrated above, the proposed reagents that would be used during mineral processing would not adversely affect water quality in the surrounding environment.

## Existing Mine Waste Fill at the Brunswick Industrial Site

Several commenters state that the number of samples for arsenic in existing rock and tailings at the Brunswick site is insufficient and that half of the Brunswick Site was not sampled for toxic metals. Figure 4.7-1 of the DEIR shows sampling locations conducted by NV5 inside the estimated boundary of historic waste rock fill as delineated on the figure. Areas outside of the sampled area of the Brunswick Site either would not be disturbed by the Project or are not potentially contaminated with historic mine waste rock. Therefore, the sampling of these areas of the Brunswick Site is not necessary. As discussed on page 15 of the Phase I-II ESA (Appendix J of the DEIR), the mine waste rock reportedly originated primarily from the New Brunswick Mine portion of the Idaho-Maryland Mine, which is known to have low arsenic concentrations, and also from the Empire Mine, which is known to contain elevated arsenic concentrations (see page 15 of Appendix J of the DEIR). As discussed on page 38 of the ESA, the mixed soil and rock fill beneath the southeastern paved area contain total and soluble arsenic concentrations that exceed regulatory benchmarks. Based on the higher arsenic concentrations and anomalous acid Based Accounting (ABA) results for this material, the geotextile fabric incorporated into the fill, and historical aerial photographs that suggest the grading was performed after mining operations were suspended, the material was likely imported to the site and did not originate from mining operations at the New Brunswick Shaft. As such, the DEIR's conclusion is based on evidence, not on mere speculation. Commenters also state that high concentrations of arsenic are associated with nearby mining sites, and conclude that rock from the Project will also have high arsenic concentrations. However, the Idaho-Maryland Mine is a different gold deposit and hosted in different rock types than the Empire-Northstar and Lava Cap Mines. Arsenic levels from samples taken in various rock types at the Idaho-Maryland Mine Project are low. (see Section 4.4 of Appendix K.2 of the DEIR.)

As a result, the level of Brunswick fill analysis conducted for the DEIR is sufficient to determine potential water quality and human health effects from historic contamination. The DEIR concludes that impacts would be less-than-significant with implementation of mitigation (DEIR, pg. 4.7-35, Mitigation Measure 4.7-2(a)).

### Conclusion

The transportation of explosives in the United States is highly regulated and has an excellent safety record. Hauling of explosives for the project would occur using Brunswick Road to State Routes (SR) 20/49, which are designated as explosive transport routes by the CHP. The DEIR correctly concludes that the project's routine transport of explosives would result in a less-than-significant impact after implementation of mitigation.

This master response also demonstrates that the DEIR correctly concludes that proposed reagents in the project's mineral processing are not highly toxic to aquatic organisms and would not impact environmental water quality due to the closed system of the processing plant.

As shown in this master response, the DEIR adequately evaluated the Brunswick fill and includes sufficient mitigation to ensure that significant impacts to human health and water quality would not occur from Brunswick fill.

## Master Response 11 - Engineered Fill Utilized in Local and Regional Construction Markets

### Comments

Several commenters questioned whether there is a market for the barren rock and sand tailings material that will be sold after the engineered fill pads at the Brunswick and Centennial Sites are filled. Market demand per se is not a CEQA issue. However, many commenters expressed concerns about indirect effects of insufficient market demand for the project's engineered fill, such as the resultant need to stockpile barren rock and sand tailings on-site. Concerns have been expressed that the DEIR does not evaluate on-site stockpiles of overburden and the potential water quality impacts that could result if the material is contaminated.

In the event that there is market demand for engineered fill at off-site locations, several commenters expressed concern about the potential water quality impacts that could occur if project engineered fill (barren rock and sand tailings) is hauled to off-site locations and is contaminated.

### Discussion

As described in Section 3.0 of the DEIR, after full placement of fill at the Centennial and Brunswick Industrial Sites to the pad design elevations, hauling of engineered fill (barren rock and sand tailings) would shift entirely to be utilized in local and regional construction markets.

As stated on page 4.8-50 of the DEIR, testwork completed on mine materials indicates that mine materials will likely be classified as Group C mine waste for the purpose of placement of engineered fill on the Centennial and Brunswick Sites. The proposed project would produce mine waste with lower sulfide and metal content than those produced historically, and the historic mine waste has been determined to be Group C mining waste from which any discharge would be in compliance with the applicable water quality control plan, including water quality objectives other than turbidity. Please see Master Response 9 - Historical Mine Waste at Centennial Site. The barren rock and sand tailings would undergo testing as part of obtaining WDRs for use in the engineered fill pads, and compliance with water quality objectives will need to be demonstrated

to the CVRWQCB prior to that placement (see Master Response 8 - Mine Waste Characterization).

Barren rock and sand tailings which are utilized in local and regional construction markets would be a mining product and not considered mining waste in the DEIR, except for purposes of formal characterization (Group A, B, or C), as required by the CVRWQCB, pursuant to Title 27 of the California Code of Regulations. [4] Nonetheless, as noted by the CVRWQCB in its April 4, 2022 comment letter on the DEIR, Rise would be required to include testing of the material to be sold for offsite use in the Characterization Plan that the CVRWQCB will require as part of the Report of Waste Discharge for the Project to ensure that such material would not pose a threat to water quality. While the material to be sold offsite would not be considered a mining waste, the CVRWQCB's requirement for testing to ensure no threat to water quality is analogous to the requirements for material to be considered Class C mining waste. Given the results of the testwork completed for the Project, which shows material is likely to meet requirements for Class C mining waste (i.e., no threat to water quality), any discharge related to use of barren rock and sand tailings for construction purposes is expected to be in compliance with the applicable water quality control plan, including water quality objectives other than turbidity. Further, through the WDR process for placement of engineered fill, including the Characterization Plan that will require testing of material to be sold offsite, the barren rock and sand tailings will be thoroughly tested sufficient to determine its suitability for use as construction aggregate, and such testing will be under the authority of the CVRWQCB.

Prior to mining in any underground area, as part of mine planning, samples would be collected through underground core drilling and would then be tested for gold content and evaluated for chemical composition to confirm that it is similar in chemical composition to other material that has already been shown to meet Class C mining waste standards. Rock types that are significantly different than those previously shown to meet Class C mining waste standards would not be mined until mine waste characterization has been performed to ensure the rock will be suitable for offsite sale. Rock types that are not suitable for offsite sale would likely not be mined, and if mined, the waste rock would be placed underground. Waste rock and sand tailings from rock types found unsuitable for construction aggregate use due to water quality impacts would not be sold as construction aggregate. Mitigation Measure 4.8-1(e) has been modified in the FEIR to state that only mining products previously classified as Group C mining waste will be utilized for local and regional construction projects. As stated in the comment letter from the Central Valley Regional Water Quality Control Board, mining waste that is characterized and classified as Group C (i.e., discharge of the wastes that would be in compliance with water quality objectives other than turbidity) could be used as engineered fill with limited regulatory restrictions. The revised language of Mitigation Measure 4.8-1(e) is set forth below (additions in <u>double underline</u>, deletions in ~~strikeout~~):

> The applicant shall submit a RoWD and obtain WDRs from the Central Valley RWQCB for construction of the engineered fill areas. The WDR permit shall be received by the applicant prior to initiating any engineered fill placement activities at the Centennial or Brunswick Industrial Sites. Proof of coverage shall be provided to the Nevada County Public Works

[4] Barren rock (with no gold values and not processed) is differentiated from mineralized rock (with gold values which is processed) in the DEIR to facilitate an understanding of the proposed project. Barren rock is also proposed to be sold in some cases and therefore would be a mineral product and not waste rock. The tailings particles are primarily of sand size gradation (DEIR, Appx. H.1, p. 14.) and therefore sand tailings is an appropriate description in the DEIR. Barren rock and sand tailings are compacted in lifts to engineering standards in order to provide a useful surface appropriate for construction of future buildings on the sites and is therefore described as engineered fill. "Waste rock" is generally used in the DEIR to refer to rock removed from the mine, but not used for engineered fill purposes.

Department. As part of this process, the RWQCB will determine the appropriate mining waste classification for the proposed engineered fill, and will consider the following factors: (1) whether the waste contains hazardous constituents only at low concentrations; (2) whether the waste has no or low acid generating potential; and (3) whether, because of its intrinsic properties, the waste is readily containable by less stringent measures. The engineered fill areas shall be constructed in accordance with the Title 27 specifications, pursuant to the mining waste classification determined by the RWQCB. The applicant shall submit to the Nevada County Planning Department a copy of the RoWD and evidence of the applicant's receipt of WDRs prior to the placement of fill or fill site preparation disturbance at the Brunswick Industrial Site and Centennial Industrial Site. The RoWD must also include a report on the physical and chemical characteristics of the waste, in compliance with Water Code section 13260(k), that could affect its potential to cause pollution or contamination as well as a report that evaluates the potential of the discharge of mining waste to produce, over the long term, acid mine drainage, the discharge or leaching of heavy metals, or the release of other hazardous substances. The WDR's will require continuous and routine characterization and classification (Cal Code regs Title 27 section 22480(b)) of the mining waste to evaluate any possible changes in the geological or geochemical nature of the waste. The applicant shall prepare and implement a Waste Characterization Plan (Characterization Plan) which shall be incorporated into the approved WDR. The purpose of the Characterization Plan is to continually evaluate the different forms of mining wastes and to appropriately classify these wastes as Group A, Group B, or Group C based on an assessment of the potential risk of water quality degradation posed by each waste. Through the WDR these wastes shall be required to be managed, treated, stored, or disposed of in a manner that is protective of water quality. The applicant shall not sell or utilize waste rock and tailings from the Project for construction aggregate or fill purposes offsite (i.e., sites other than the applicants Brunswick and Centennial sites) unless such material has been tested and confirmed to qualify as Group C mining waste under California Code of Regulations Section 22480 and the approved WDR. The specific methods, volumes and frequency of characterization shall be established in the approved WDR.

The above changes to Mitigation Measure 4.8-1(e) are for clarification purposes and do not alter the conclusions of the DEIR. See also Response to Comment Agcy 5-4 (CVRWQCB Letter).

## Evidence for Market Demand

The DEIR assumed that trucking of rock and sand would occur up to 60 miles, one way, from the Project site. This distance allows access to a large market area including most of Nevada County, and the Sacramento-Roseville region. These areas have demand for aggregate of over 25 million tons per year according to the California geological Survey,[5] as summarized in Table 2 below. The Project would produce approximately 182,500 tons of rock and 182,500 tons of sand per year, which is less than 2% of the yearly market demand for this area. Importantly, the Sacramento County aggregate production-consumption area has less than 50% of its 50-year aggregate demand currently permitted, which means there is a long-term shortage of construction aggregate and therefore a long-term market for the barren rock and sand tailings produced by the Project in that region. (see California Department of Conservation Mapsheet 52, 2018.) Specifically, Sacramento County had 327 million tons permitted of the anticipated 724 million ton 50-year demand as of the publication of Mapsheet 52 in 2018 by the California Department of Conservation.

[5] https://www.conservation.ca.gov/cgs/Documents/Publications/Map-Sheets/MS_052_California_Aggregates_Map_201807.pdf

**Table 2**
**Aggregate Demand within range of IMM Project**

| | |
|---|---|
| Nevada County | 820,000 |
| Yuba City-Marysville | 6,880,000 |
| Placer County | 3,760,000 |
| Sacramento County | 14,480,000 |
| **Total** | **25,940,000** |

No large-scale temporary rock or sand storage facilities/stockpiles are proposed for the Project. The only storage of barren rock or sand tailings would be the temporary storage of materials at the Brunswick Shaft, inside the process plant, and at the Brunswick and Centennial Sites where material would be dropped by trucks and later graded and compacted during weekday daylight hours. If the Project's proposed engineered fill sites and the Brunswick and Centennial Industrial Sites were complete and there was low demand for barren rock or sand tailings, or the material was unsuitable for construction use, the operation would by necessity reduce or halt generation of these materials until an appropriate market, such as fill material or other use of rock material for which the material met appropriate specifications, could be identified. However, an adequate market for sale of the barren rock and sand tailings is expected, given the location of the Project site in proximity to the Sacramento market, which has an undersupply of construction aggregate.

### Conclusion

This master response demonstrates that there is sufficient market demand for engineered fill (barren rock and sand tailings) after full utilization of the Centennial and Brunswick Sites engineered fill piles, thus, eliminating the need for on-site aboveground stockpiles. This response also demonstrates that the DEIR correctly concludes that the use of engineered fill at off-site locations would not result in adverse effects to water quality due to compliance with applicable State regulations, as required in DEIR Mitigation Measure 4.8-1(e).

## Master Response 12 - Chemical Dust Stabilizers

### Comments

Several commenters have raised concerns about the generation of dust from project construction and operations and resultant air quality effects. Select commenters have also asked for details on the composition and environmental effects of chemical dust stabilizers proposed to be used for the reduction of dust on unpaved haulage roads for the Project.

### Discussion

The Project would use industry standard polymers as a chemical stabilizer to reduce haul road dust. This control type is highly efficient (74% to 94% dust control efficiency) with application approximately bi-weekly (see Table 11.1 of NIOSH 2nd edition Dust Control Handbook for Industrial Minerals Mining and Processing)[6]. These chemicals are not toxic air contaminants and therefore do not require evaluation in the Health Risk Assessment. Research by the US EPA has shown that these types of dust suppressant products have minimal to no adverse impacts on water quality and aquatic life relative to the use of water alone[7].

[6] https://www.cdc.gov/niosh/mining/UserFiles/works/pdfs/2019-124.pdf
[7] https://19january2017snapshot.epa.gov/www3/region9/air/dust/DustSuppressants-sept2008.pdf

Applicant Proposed Measure (APM) AQ-2 requires that during construction, all on-site roadways shall be paved as soon as possible after grading and any unpaved gravel roads shall be treated with chemical stabilizers in order to control fugitive dust (see page 4.3-65 of the DEIR). This measure will be required as a mandatory condition of approval for the Project. The air quality model presented in Appendix E.1 of the DEIR assumes the use of chemical stabilizers for reduction of dust by 80% for vehicle traffic on certain unpaved roads during construction (see page 300 of Appendix E.1). Notably, chemical dust stabilizers are not assumed for emissions reductions from unpaved roads during operations in the DEIR. This is a conservative assumption as dust emissions from vehicle traffic on unpaved access roads are estimated at 18.7 pounds per day (see page 303 of Appendix E.1) with the use of water for dust suppression (55% dust control efficiency). If chemical stabilizers are used for unpaved access roads during operations a substantial reduction in dust may be achieved versus the assumed emissions for the analysis in the DEIR.

From a health perspective, the Health Risk Assessment (HRA) prepared for the proposed project ((included in Appendix B of Appendix E.1 of the EIR) evaluated fugitive dust as $PM_{10}$. The HRA concluded that a significant health hazard to the public would not occur as a result of fugitive dust after implementation of mitigation (see DEIR, p. 4.3-82). For more detail, please refer to Master Response 20 – Conservatism Used for Metals in Dust, Master Response 21 – Silica Health Risk, and Master Response 22 – Conservatism Used for Asbestos Assessment.

### Conclusion

This master response confirms that the proposed project will use chemical dust stabilizers that are not considered toxic air contaminants, nor do they have adverse effects on water quality or aquatic life. This response also demonstrates that, after implementation of mitigation, the project's construction and operations would not expose sensitive receptors to substantial concentrations of fugitive dust such that a human health effect would occur (Appendix G, III(c)).

## Master Response 13 - Historic Hydrogeologic Assessments

### Comments

Several commenters have questioned why the hydrogeologic analysis in the Rise Gold DEIR is different than that used in the prior 1995 and 2008 EIRs produced for the Emperor Gold and Emgold projects; and specifically questioned why the area of potential dewatering impact is different (i.e., reduced) in the current analysis. As discussed below, the 1995 and 2008 EIRs relied on less sophisticated groundwater models that did not account for regional groundwater flow or the impact of streams, which resulted in a less accurate analysis and slightly different conclusions regarding the area of dewatering impacts.

### Discussion

The Idaho-Maryland mine has been the subject of two previous environmental impact reports in 1995 and 2007 by Emperor Gold and Emgold, respectively. The current applicant, Rise Grass Valley, is not affiliated with the previous applicant.

The Groundwater Model (2020) prepared by Itasca (Appendix K.3 of the EIR) is a groundwater flow model that was constructed to solve 3-D groundwater flow problems using the finite-element method. The model simulates hydrostratigraphic units, rivers and creeks, precipitation and recharge, underground workings, and historic mining. The groundwater model was calibrated on historic groundwater inflows into the mine, the current and historical water level in the Union Hill Mine, the current water level in the New Brunswick Shaft, ground measured water levels in domestic water wells in the area and base flow rates of Wolf Creek and South Fork Wolf Creek.

Previous hydrogeological assessments did not use groundwater models and relied on less sophisticated analytical solutions to estimate impacts to domestic water wells. Consequently, the prediction of ground water drawdown is much more in-depth, robust and reliable than previous assessments. Nevertheless, despite the simplified analytical solutions used by previous assessments, these assessments came to similar conclusions regarding the potential area of impact to domestic water wells as the current analysis.

In the 1995 EIR, Sierra-Pacific Groundwater Consultants, prepared a hydrogeological assessment of the potential impact of mine dewatering on domestic wells. In that assessment, an analysis was conducted involving the distance from the bottom of the well to the nearest underground mine working and estimates of inflow and outflow of groundwater (Q) at each well location. An unconventional method was used in the determination of each component of the Darcy equation which was used to estimate inflow and outflow for each well. Notwithstanding the unconventional application of data to Darcy's Law, the results of the analysis indicated that wells closest to the workings were at greatest potential risk for dewatering impacts. (pages 18-19, Todd 2007). In the 1995 Emgold Final EIR, 15 wells were considered High Risk, with partial and complete dewatering highly probable, and 2 wells Moderate Risk with partial dewatering of wells probable and complete dewatering of wells possible. Other wells in the Study Area were categorized as low or very low risk wells with partial dewatering of wells improbable and complete dewatering of wells highly improbable. The Study Area and wells from the 1995 Final EIR are shown in Figure 9 through Figure 14 below. As shown on Figure 9 and Figure 10, the majority of the wells considered High or Moderate Risk for dewatering impacts in the 1995 EIR are in the E. Bennett Road area, in which the current project proposes to connect to the NID potable water system. The 1995 EIR also found five wells south of E. Bennett Road and nearby South Fork Wolf Creek (Wells #128, 240,113,233,236)[8] to have dewatering impacts; however, these wells were not found to have the potential for significant dewatering under the Itasca model used in the DEIR. The 1995 hydrologic assessment does not model the regional groundwater flow and simulations of streams, which is why these five additional wells were found to have dewatering impacts in 1995. Conversely, by using a comprehensive Groundwater Model, rather than simplistic analytical methods used in 1995, Itasca determined that the influence of a shallow groundwater table and recharge from South Fork Wolf Creek limits groundwater drawdown in the valley bottom south of E. Bennett Road, resulting in no significant dewatering impact to these 5 wells south of E. Bennett Road and nearby South Fork Wolf Creek. Please see Master Response 33 – Groundwater Dependent Vegetation.

In connection with the 2008 EIR for Emgold, Todd Engineers prepared a hydrogeologic analysis that estimated an impact area using an analytical equation which assumed the mine workings would behave as a pumping well within the groundwater system. Todd estimated that a cone of depression would form and declines in the groundwater system could be anticipated in a zone of approximately 710 feet around the mine workings. Todd used the formula $r^2 = 0.3Tt/S$, where r= distance to the point of zero drawdown, T = transmissivity, t = time for the cone of depression to reach steady state, S = storativity of the aquifer. Todd uses a T value of 84 gpd/ft, S value of 0.01, and t of 200 days to calculate a radius of 700 feet. A conservative and simplifying assumption is made that the zone of impact will expand equally away from the outer edge of all the workings regardless of depth of extent of workings. As such, the calculated radius of influence was applied to all areas of the workings, no matter how deep or small in volume the workings may be in some areas. Eighteen wells were considered to have the highest potential risk of impacts from

[8] Note that Figure 1 shows Well #205 as a high risk well but this well is not present in the high and moderate risk tables and is an error in the historic figure. This well is in the very low risk table of the 1995 Final EIR.

dewatering and Todd concluded that actual impacts will likely be less than predicted due to the conservative nature of the analysis. (pages 20-22, Todd 2007).

As shown in Figure 15, the area of potential impact in the 2007 Todd report included the E. Bennett Road area and extended approximately 0.5-mile east of Brunswick Road. As noted previously, the radius estimated by Todd was to the point of zero drawdown and no attempt was made to quantify whether an insignificant amount of drawdown would actually impair the use of a domestic water well. Todd conducted a sensitivity analysis by increasing pumping time from 200 days to 730 days to illustrate how increased pumping would impact the analysis with a resulting radius of influence increased to 1,356 feet. (see page 23 of Todd 2007). This sensitivity scenario was used in the 2008 Emgold DEIR which categorized 18 wells as high-risk wells and 18 wells as moderate risk wells. (see page 4.7-33 and Figure 4.7-3 of ESA 2008). Figure 16 below shows the Areas of Potential Impacts from the 2008 DEIR. The extended area of impact, to the point of zero drawdown, used in the 2008 DEIR is similar the 2-foot drawdown contour predicted by the Groundwater model for the current Rise Gold DEIR (see Sheet 12 of Appendix K.2).

Notably, Todd Engineers submitted a comment letter on the 2008 DEIR and disagreed with the 2008 EIR preparers use of its sensitivity scenario by ESA to categorize risks to wells and stated "Based on the analyses in our 2007 report and in this memorandum, it is not technically defensible to expand the zone where the highest level of mitigation would be required. We recommend that the 710-foot zone, in addition to the area of the workings footprint, be maintained as the area with the highest level of mitigation for a permanent surface water supply." In other words, Todd's opinion was that the 2008 EIR inappropriately expanded the likely area of dewatering and associated groundwater impact based on a mischaracterization of its report.

Todd also stated that the lone drift (underground tunnel) at the 1,100-foot below surface level that extends east of Brunswick Road would not likely contribute to water level decline during dewatering. (see page 5 of Todd comment letter – Todd 2008). In its comment letter, Todd provided a revised figure, shown as Figure 17 below, which shows the high and moderate risk areas recommended for a permanent water supply, generally confined to the E. Bennett Road area. This is a very similar result to the conclusions of both the 1995 hydrogeologic study and the current DEIR.

## Conclusion

The conclusions of the hydrogeologic analyses used in the 1995 and 2008 EIRs are substantially the same as the conclusions in the Rise Gold EIR, and there are only minor differences in the overall conclusions, which are explained by the different modelling methods. In general, the practical result of these differences is that the previous hydrogeologic assessments predicted more wells would be impacted by dewatering as compared to the current DEIR's findings. However, as shown above, the number of impacted wells is not substantially greater than that which is predicted in the current DEIR, and said DEIR includes mitigation measures (MMs 4.8-2(a-c)) to ensure that impacts to groundwater wells (Appendix G, X(b)) are reduced to a less-than-significant level.

# Master Response 14 - Adequacy of Groundwater Model

## Comments

Several commenters disagree with the methods and conclusions of the groundwater model, asserting such things as the model is not appropriate for use in fractured rock, the data from private wells is old and not sufficient for modelling purposes, and the modelling period does not represent the full 80-year operational life of the mine. This master response demonstrates that the groundwater model (MINEDW) used to predict the project's potential impacts to groundwater (Appendix G, X(b)) is a robust model that has a long history of use with accurate results, and is appropriate for use in evaluating the dewatering effects of the proposed project.

## Discussion

As stated in Section 4.0 of Appendix K.3 of the DEIR, the groundwater flow model that was constructed for this investigation utilizes the numerical code MINEDW, which was developed by Itasca (2012) to solve 3-D groundwater flow problems with an unconfined (or phreatic) surface using the finite-element method. MINEDW is a commercial software that was thoroughly reviewed by Sandia National Laboratories (Corbet et al. 1998). MINEDW has been used at more than 100 mine sites located throughout the world and in diverse hydrogeologic and climatic conditions. MINEDW has been in use for approximately 30 years, and its predictions have been validated by field data collected over many years (see Appendix A of Appendix K.3 of the DEIR) and recognized as valid by the Nevada Division of Environmental Protection for use in permitting applications.

### MINEDW Model is Acceptable Industry Practice for Use in Fractured Rock

Several commenters have stated that the model is not appropriate for use in a fractured rock. The conceptual model proposed by Itasca, in simple concepts, is that the shallow bedrock is significantly fractured so that it behaves hydraulically like a porous media. This is consistent with analysis of well data (see Section 3.3 of Appendix K.2 of the DEIR). Below the shallow, fractured bedrock is the intact bedrock whose fractures are closed due to the vertical stresses caused by the overlying bedrock. The intact bedrock also behaves as a porous media in that groundwater flow is primarily through the extremely small pores in the rock. Itasca assigned low hydraulic conductivities and storage coefficients to the intact bedrock in which mining will occur. The application of a continuum (porous media) approximation is applicable to mining projects in that it is used generally to estimate flows from the mine and drawdowns in water levels due to dewatering, a situation similar to predicting well yields. Please see Reponses to Individual Letter 232 for an in-depth discussion on this topic.

The MINEDW for the DEIR was calibrated on historic groundwater inflows into the mine, the current and historical water level in the Union Hill Mine, the current water level in the New Brunswick Shaft, ground water levels measured in domestic water wells in the area, and base flow rates of Wolf Creek and South Fork Wolf Creek. As described in Section 4.6 of the Groundwater Model Report (Appendix K.3 of the DEIR), Itasca conducted transient model calibrations by matching the change of groundwater levels at the Union Hill Mine and groundwater inflows to the historical mines. The simulated and measured ground water levels from domestic water wells in the area and the measured water level in the New Brunswick shaft were compared. The simulated groundwater levels were within the ranges of measured water levels for domestic water wells in the area and the simulated mine-water level is essentially the same as the measured water level in the New Brunswick shaft. The hydraulic conductivity (K) values derived from the groundwater flow model calibration for different geologic units were found to be within the ranges of the estimated K values and literature values.

## Private Well Data Used in Model

Several commenters state that data from private wells is old and is limited to a few years without usage data provide. Contrary to the commenters' assertions, water level data has been collected for many years over a period spanning two decades. As stated on page 26 of Appendix K.2, monitoring of water level in wells for up to 79 wells was undertaken from 1995-2001 and 2003-2007. As noted in the report, no long-term increasing or decreasing trends are observed in the data. Therefore, the age of the sample data does not limit the usefulness of this data. Nevertheless, no groundwater level measurements have been completed since 2007, which creates some uncertainty to the predicted impact to percentage of water column in domestic wells. Uncertainty in predicted impacts is addressed through the various sensitivity scenarios discussed in Appendix K.3, the application of a 100% factor of safety (see page 4.8-58 of the DEIR), and the proposed connection of all 30 properties, including properties where no significant impact is predicted, in the E. Bennett area to NID potable water (see page 4.8-66 of the DEIR). Despite this, the analysis in Chapter 4.8 of DEIR has determined that the Project could result in a significant impact to groundwater supplies without implementation of a groundwater monitoring program and well mitigation plan. Mitigation Measure 4.8-2(a) requires that a minimum of 12 months of water-level monitoring data is collected before commencement of dewatering. Impacts to domestic water wells will be measured against those current baseline measurements and not historic water levels. Mitigation Measure 4.8-2(b) requires well mitigation if, based the groundwater monitoring plan, a 10 percent reduction in the water column of a well is determined. Therefore, the determination of impact would be based on current water level data and any impacts to domestic wells would be mitigated through the proposed mitigation measures. As stated on page 4.8-67 of the DEIR, implementation of Mitigation Measures 4.8-2(a), (b), and (c) would reduce the project's groundwater impacts to a less-than-significant level.

## Model Calibration

Several commenters believe that more flow measurements from the mine drains are required for calibration of the groundwater model. However, the current flow rate of mine water from the drains was not used for the calibration of the groundwater model. The current flow rate of mine water from the drains was not used for the calibration of the groundwater model because the preferential pipe flow in the mine workings is not simulated in the model and the purpose of the model is to calibrate to "current" groundwater levels, based on measurements taken from 1994 through 2007, and the current water level in the mine which is controlled by the drain outlet elevations. Additionally, there could be additional preferential recharge from surface runoff through mine workings reporting to the drains. This extra recharge, not related to groundwater flow, is not quantifiable and could result in inaccurate calibration of the groundwater model. Accordingly, the

commenters' requests for inflow/outflow data is not relevant to the groundwater model and the assessment of groundwater impacts.

### Modelling the Project's Long-Term Mining Effects

Several commenters assert that the groundwater model should be run for an 80-year period rather than 65 years. The groundwater model was based on the expected mining plan during year one to year 25, and then Sensitivity Scenario 6 considered the significant expansion of mining in areas with potential for mineralization as shown in Figure 5.10 of Appendix K.3 of the DEIR for an additional 40 years of mining. As shown in Figure 5-12, and discussed on page 29 of the report, the 5-ft drawdown contour extent of Scenario 6 at the end of potential additional mining (to Year 65) relative to the 2019 water level expands less than 500 ft from that of the Base-Case Scenario. The drawdown contour of the Base-Case Scenario is at the end of the original planned future mining (Year 25) relative to the 2019 water level. The comparison of drawdown contours between Scenario 6 and the Base-Case Scenario confirm that the added potential mining (beyond the 65 years modeled) will not lead to significant incremental drawdowns as the mining progresses because the mining activities occur in deep, low hydraulic conductivity rocks. The decrease in fractures and hydraulic conductivity with depth is well documented. As stated on page 4.8-8 of the DEIR, the U.S. Geological Survey (Page et al., 1984) conducted a study covering a 148-square mile area of southwestern Nevada County, including the segment of the Wolf Creek watershed from Grass Valley to the Bear River. The underlying bedrock consisted of similar rock types to those encountered at the project site, including hard, dense metavolcanic and igneous rocks of pre-Tertiary age. The study results found that the degree of fracturing in the bedrock, and thus the well yield, decreases with depth, with most of the available groundwater occurring above a depth of 215 feet below the ground surface (bgs). At depths shallower than 215 feet bgs, 70 percent of the wells evaluated produced more than five gallons per minute (gpm). However, at depths deeper than 215 feet bgs, 75 percent of the wells produced five gpm or less. As stated on page 4.8-16 of the DEIR, EMKO reviewed 38 well completion reports within a 1- to 2-mile vicinity of the Project, which contained information regarding the total drawdown that occurred and the pumping rate achieved during initial testing of the wells immediately after they were drilled. A clear correlation exists between pumping rate and depth. The maximum pumping rate achieved was 125 gpm in a well with a total depth of 123 feet bgs. In contrast, at depths of 200 feet or deeper, the maximum reported pumping rate is 50 gpm. Below a depth of 300 feet, the maximum pumping rate reported was 10 gpm, and below a depth of 450 feet, the maximum pumping rate reported was only four gpm. Similarly, Todd Engineers (2007) developed a relationship between the hydraulic conductivity and depth based on information from approximately 300 driller reports. Todd Engineers (2007) found that the hydraulic conductivity of the fractured bedrock penetrated by the domestic supply wells in their study area varied significantly with depth, with greater values at shallower depths where more fractures are prevalent, and with much lower values at deeper depths, where fractures may be either less common or have smaller aperture (open) widths.

Thus, the DEIR and the associated groundwater modelling for the proposed project adequately addresses the full potential extent of the project's groundwater impacts as required in Appendix G, X(b).

## Conclusion

As stated on page 4.8-41 of the DEIR, the County's independent expert West Yost found that the groundwater model was acceptably calibrated pursuant to industry practices, and adequately represented the Project's expected impacts. Accordingly, the DEIR contains concurrence of multiple experts on the suitability of the groundwater model and as such, constitutes substantial evidence of the significance determination that, after implementation of mitigation, the proposed

project would result in a less-than-significant impact related to substantially decreasing groundwater supplies (Appendix G, X(b)).

## Master Response 15 - Adequacy of Groundwater Monitoring Wells

### Comments

Several commenters have questioned the adequacy of the Groundwater Monitoring and Mitigation Plans required for the Project. The majority of concerns focus on 1) the use of a groundwater monitoring well network in the potential area of drawdown, rather than direct monitoring of domestic wells in the area; and 2) lack of monitoring throughout the entire mineral rights area. The alleged implication of the above concerns is that the groundwater monitoring required for the proposed project is inadequate, and thus, will not detect the full extent of wells that will be impacted by the project's dewatering.

### Discussion

The analysis in the DEIR concludes that the proposed mining operations could result in adverse effects to seven domestic water supply wells in the East Bennett area during the life of the mining operation (see page 4.8-66 of the DEIR).

#### Groundwater Monitoring Plan

A rigorous groundwater monitoring plan (GMP) will be implemented by the applicant to assess how the hydrogeologic system responds to mining. This response to dewatering cannot be measured until mine dewatering commences; however, Mitigation Measure 4.8-2(a) requires that the monitoring wells be installed prior to dewatering. Mitigation Measure 4.8-2(b) requires that if it is determined, based on the GMP, that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified. Mitigation measures are achievable, enforceable, and capable of reducing the Project's impacts. The GMP along with the requirement that the applicant provide water to 30 parcels and provide water to any other parcels with wells that are impacted by the Project ensures that the mitigation is enforceable by the County, achievable through water supply replacement requirements, and capable of reducing the Project's impacts.

Several commenters assert that groundwater monitoring networks need to be installed prior to dewatering. This is already required at least 12 months in advance per Mitigation Measure 4.8-2(a). This water level monitoring will provide the baseline levels prior to dewatering. The collection of 12 months of baseline data allows for the seasonal change in water levels at each location to be captured. As described in Section 3.3.2.2 of Appendix K.2 of the DEIR, the water levels in the private domestic wells have seasonal fluctuations between wet and dry times of the year but have remained relatively consistent from year to year within each individual well. No groundwater level measurements have been completed since 2007. However, impacts to domestic water wells will be measured against the current measurements of water levels, collected in the 12-month period, and not historic water levels.

The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. The collection of water quality information, as discussed in Section 8.0 of Appendix K.8, from the proposed monitoring wells would also be completed and would be representative of the baseline

water quality in domestic water wells in the area. Hydraulic testing of monitoring wells would be conducted as described in Section 6.0 of Appendix K.8.

As previously noted, a GMP is required for the project under Mitigation Measure 4.8-2(a). As described on page 4.8-66 of the DEIR, the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Monitoring wells will be specifically designed and constructed for monitoring purposes. Use of monitoring wells is preferable to monitoring of domestic wells because of uncertainties in the design, construction and operating conditions in domestic wells (pages 2-3 of the GMP, Appendix K.8 of the DEIR). The monitoring wells will be representative of the surrounding domestic water wells because they will be constructed at representative locations and depths.

As stated in Section 3.0 of the GMP, the drawdown caused by Project dewatering will propagate outward over time. Monitoring wells in closer proximity to the mine will generally experience drawdowns before wells farther away. The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. As discussed in the GMP, 30 groundwater monitoring wells will be installed at 15 locations. The locations of the monitoring wells are strategically placed between the mining zone and domestic wells to monitor the potential drawdown extent as the result of mining and assess the potential impacts on domestic wells. As stated in Section 7.0 of Appendix K.8, each monitoring well will be equipped with a downhole submersible data logger that will record water levels over time. The data logger will be programmed to collect water-level information on a periodic basis, such as once every 1 to 4 hours. As stated on page 10 of Appendix K.8, drilling and well installation activities will be performed under the supervision of a California-Registered Geologist. Qualified hydrogeologists would evaluate the data from groundwater monitoring.

Groundwater drawdown will be measured at the proposed monitoring wells and then used, in conjunction with data collected by the Domestic Well Monitoring Program (see below), to predict an impact to a domestic water well before any well production impact from dewatering could occur. The impact will be determined using the threshold set forth in the Well Mitigation Plan.

## Water Quality Monitoring

Several commenters have raised concerns that their well could be contaminated by mine dewatering through the outward flow of alleged contaminated groundwater within underground mine workings. As stated on page 4.8-48 of the DEIR, the, dewatering causes a low-pressure area around the underground workings such that groundwater inflow is toward the mine, not away from the mine toward the domestic wells. Blasting or backfilling with CPB would be conducted exclusively within the underground mine workings. Thus, any water that contacts those components would be present only within the mine workings and would be then pumped out of the mine workings by the dewatering system and into the clay-lined pond for further water treatment. As a result, that water would not have the potential to flow into the fractured bedrock and flow toward any domestic supply wells. The primary residual components of the ammonium nitrate-fuel oil (ANFO) used for blasting, ammonia and nitrate, are very soluble and mobile in water. This means that any blasting residuals would be continually removed from the mine over time through the dewatering system. Thus, when the mine is allowed to flood again following the completion of mining, there is no reasonable potential that residuals from former blasting activities would cause a violation of any water quality standards or waste discharge requirements or

otherwise substantially degrade surface or groundwater quality. As stated on page 4.8-51 of the DEIR, the proposed mining areas would primarily be at equivalent or deeper depths than the existing underground mine workings, while the potential future expansion areas all involve mining at greater depths, typically more than 1,000 feet below the surface and deeper. At those greater depths, the hydraulic conductivity is several orders of magnitude lower than it is at the depths of the domestic supply wells, due primarily to the lack of open fractures as a result of the large pressures exerted by the overlying rock mass (i.e., the lithostatic pressure). Given that the new mining activity would occur at equivalent or greater depths than the proposed mining, there is little or no potential for the proposed mining and mining in the future expansion areas to affect the quality of the groundwater in the domestic supply wells that are completed at much shallower depths.

Notwithstanding the above, as noted below in this master response, to provide property owners additional assurance regarding impacts of mine dewatering, a condition of approval will be imposed on the Project requiring that monitoring of domestic water wells will be conducted upon request for property owners within or nearby the predicted 1-ft drawdown isopleth of the Project. These 378 properties are listed in Table 3 and shown in Figure 18 below. Included in this Domestic Well Monitoring Program is water quality sampling to monitor potential changes in water quality over time.

## Well Water Quality Would Not be Impacted from Changes in Groundwater Flow Paths

Several commenters expressed a concern with the potential water quality degradation in domestic wells that may be caused by lowering of the water table and associated changes in groundwater flow paths. In response, Itasca prepared several figures of the modelled water levels at three time periods (attached to the FEIR as Appendix C); Pre-mining (before any historical mining activity), 2019 (the present/baseline condition), end of future mining (after 25 years of mining). The water levels are shown at a larger scale using 50-foot contours. However, the figures demonstrate that the drawdown during mining only has a minor effect on a few of the contours, and at a very local scale. The overall regional groundwater flow paths are not altered. As such, there would not be sufficient changes in actual groundwater levels in wells to cause groundwater with naturally-occurring arsenic to be pulled to different locations. As demonstrated by the figures attached as Appendix C to the FEIR, water quality impacts to domestic wells due to changes in water quality flow direction would only occur if the mining changed the actual groundwater levels by hundreds of feet. There is no evidence or precedent for an effect of that magnitude. Rather, the model predicted drawdown of 10 ft is localized well within the Rise mining boundary. As such, water quality impacts to domestic wells are speculative impacts that do not require analysis under CEQA.

## Well Mitigation Plan

Mitigation Measure 4.8-2(b) requires that if it is determined, based on the GMP, that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified. As discussed in the Well Mitigation Plan, if a dewatering impact to an area outside of the East Bennett area were projected during operations, pre-emptive action would be taken as necessary to ensure immediate water supply and compensation. The 10% drawdown threshold of significance is extremely conservative and, in most cases, would not lower the water level below the casing of the domestic well.

Therefore, well mitigation may not be required after inspection. If reduction of the water column was great enough to reduce the well's yield, a simple adjustment to the pumping system may only be required. For example, by installing or increasing the size of a pressure or holding tank and pumping at a lessor rate over a longer duration, if necessary. The Well Mitigation Plan has been edited to clarify the range of actions and procedures that would be taken under the Well Mitigation Plan and the performance standards required for Well Mitigation. The revised Well Mitigation Plan is attached to the Final EIR as Appendix D.

## Analysis of Dewatering Effects Outside East Bennett Area

Several commenters have stated that the water supply for wells outside of the E. Bennet area must be analyzed in the DEIR. The analysis provided in Section 4.8-2 of the DEIR concludes that the proposed mining operations could result in adverse effects to seven domestic water supply wells in the East Bennett area during the life of the mining operation. No significant impacts to domestic water wells are predicted in other areas based on technical analyses. The predictions include the use of a 100% safety factor, multiple sensitivity scenarios, and have been peer reviewed by the County's independent expert consultant. The future mitigation of wells outside the East Bennett area, if any, and method of mitigation are speculative as the DEIR does not predict any significant impact in these areas, and CEQA does not require the analysis of speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." Therefore, as an impact of water supply to wells outside of the East Bennett area is not predicted, such analysis is speculative and need not be analyzed in the DEIR.

## Water Supply Compensation to Impacted Property Owners

Several commenters state that the applicant should pay for water for any parcel connected to NID water supply for the life of the mine, even after the parcel is sold or annexed into the City of Grass Valley. The Well Mitigation Plan (Appendix K.9 of the DEIR) takes a conservative approach and presumes that an owner who decides to connect to the NID system has been impacted by and at the fault of the mining operation, even if no impact to groundwater well supply has occurred. As such, the Well Mitigation Plan was designed to be even more conservative than Nevada County General Plan Policy 17.12, which requires an impact as a prerequisite to the obligation to pay for water, which policy states "if it is determined that the operator is at fault, impacted owners shall be compensated by the operator." A new homeowner would not be impacted because the impact would have previous occurred, and the cost of purchasing water from NID for that new homeowner would be the same as buying any other home connected to NID's water supply. The provision of free water as a selling feature to a new buyer is not contemplated by the policy. If a property was annexed into the City of Grass Valley, it would be subject to the ordinances of the City, which allows water wells to be used for irrigation purposes only (Grass Valley General Ordinance Section 13.16.020) and would therefore require a property owner to connect to the potable water supply and pay for their water use. As annexation of a home into the City would already require connection to NID water supply and purchase of NID water, continuation of payment for water by the applicant after annexation would be a windfall to the property owner rather than mitigation of an impact, and is not required by CEQA or County policy.

## Domestic Well Monitoring Program

A number of property owners in the area surrounding the Idaho-Maryland Mine Project have expressed concerns about the Project's impact on their domestic wells, both in terms of drying up their well(s) and adversely affecting well water quality.

To provide property owners additional assurance regarding impacts of mine dewatering, a condition of approval will be imposed on the Project requiring that monitoring of domestic water wells will be conducted upon request for property owners within or nearby the predicted 1-ft drawdown isopleth of the Project. These 378 properties are listed in Table 3 and shown in Figure 18 below. Some of these properties do not have a domestic water well but to ensure that well owners are not excluded all owners will be contacted by the Company. Certain areas, including the City of Grass Valley, Loma Rica Industrial Area, Tim Burr Lane / Star Drive, Cedar Ridge, The Cedars, New Brunswick Court, and Brunswick Pines are known to already be serviced by NID potable water as shown in Figure 19. Property owners in these areas will not be contacted. Please see Appendix E to this Final EIR for the Domestic Well Monitoring Program.

The following measures have been added to the Domestic Well Monitoring Program, and shall be included as a condition of approval for the Project:

1) Property owner's shown in Table 3 will be contacted at least three months prior to commencement of the required 12-month groundwater monitoring period and the company will request permission to inspect and install monitoring equipment at the well.
2) Property owners who respond and grant permission for well monitoring will be added to the Domestic Well Monitoring Program.
3) The well will be inspected to determine the characteristics of the well, including location, well depth, casing and screen depth, static water level, and well yield. A water quality sample will be taken during the inspection.
4) Instrumentation will be installed to measure water level on a periodic basis (such as 1 or 4 hours) and pumping rates (to correlate water level with the wells use). Data from the instruments will be transmitted by telemetry.
5) Water level data will be collected for at least 12 months prior to the commencement of mine dewatering and will continue throughout the period of initial mine dewatering (dewatering of the historic mine workings) and for at least the first 5 years of operations.
6) All data collected and reports generated will be provided to the property owner and to Nevada County.
7) All costs of well monitoring will be paid by the company and well monitoring equipment will remain the property of the company. A property owner may terminate well monitoring upon request and the company will remove any installed monitoring equipment.
8) For any well that is monitored under the Domestic Well Monitoring Program, monitoring results will be used to supplement the analysis from the Groundwater Monitoring Plan to determine whether an individual groundwater well is expected to be impacted or has been impacted by dewatering operations, using the threshold set forth in the Well Mitigation Plan.

### Conclusion

The DEIR (Mitigation Measure 4.8-2(a)) requires a groundwater monitoring plan that includes installation and monitoring of numerous groundwater monitoring wells to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Mitigation Measure 4.8-2(b) requires the applicant to be responsible for replacing water for any impacted wells (i.e., a 10 percent or greater reduction of the water column of any well) beyond the expected drawdown impact area, pursuant to Nevada County General Plan Policy 17.12. While the GMP is adequate to ensure early detection of potential well impacts (both quantity and quality), the applicant has agreed to implement a Domestic Well Monitoring Program, that would work in concert with the GMP to ensure early detection of potentially significant well impacts beyond the anticipated drawdown area, such that well mitigation measures can be implemented.

## Master Response 16 - Drought and Climate Change

### Comments

Several commenters have stated that droughts induced by climate change are not considered in the analysis of the DEIR or that the Project will contribute to the effects of drought on water users.

### Discussion

As disclosed in Section 3.3.2.2 of Appendix K.2 of the DEIR, the water levels in the private domestic wells have seasonal fluctuations that may range from 10 feet to 50 feet between wet

and dry times of the year but remain relatively consistent from year to year within each individual well. During the monitoring period, several years with below normal rainfall occurred (2001, 2004, and 2007), multiple years with above normal rainfall occurred (1995-1998 and 2006), and several years of near-normal rainfall occurred (1999, 2000, 2002, 2003, 2005). Despite large variations in annual rainfall from year to year, the seasonal water level cycles in individual wells remain consistent over time and the overall water levels shown on the hydrographs for each well do not fluctuate based on wet or dry climatic cycles. Based on the lack of changes in the individual well hydrographs between wet and dry climatic cycles, the amount of recharge, as described in Section 3.2, appears to be consistent from year to year and is not affected substantially by drought or wet cycles. It is noted that no groundwater level measurements have been completed since 2007 which creates some uncertainty to the predicted impact to percentage of water column in domestic wells. Uncertainty in predicted impacts is addressed through the various sensitivity scenarios discussed in Appendix K.3, the application of a 100% factor of safety (see page 4.8-58 of the DEIR), and the proposed connection of 30 properties, including properties where no significant impact is predicted in the E. Bennett area, to NID potable water (see page 4.8-66 of the DEIR). Nevertheless, the analysis in Section 4.8 of DEIR has determined that the Project could result in a significant impact to groundwater supplies without implementation of a groundwater monitoring program and well mitigation plan. Mitigation Measure 4.8-2(a) requires that a minimum of 12 months of water-level monitoring data is collected before commencement of dewatering. Impacts to domestic water wells will be measured against those current baseline measurements of monitoring wells and not historic water levels. Mitigation Measure 4.8-2(b) requires well mitigation if, based the groundwater monitoring plan, a 10 percent reduction in the water column of a well is determined. Therefore, the determination of impact would be based on current water level data and any impacts to domestic wells would be mitigated through the proposed mitigation measures.

Climate models predict that mean annual temperatures in the western United States will increase 1–2 °C during the first half of this century and the warmer temperatures will likely result in a reduction in mountain snowpack and a winter-ward shift in springtime peak streamflows of about one month by 2050. These effects are reported to have already been observed in the Sierra Nevada. However, current understanding of groundwater recharge and storage in mountain watersheds is insufficient to predict with reasonable confidence the manner and rate at which discharge from mountain aquifers will respond to changes in climate (Earman 2012). Reduced mountain snowpacks could potentially lead to reduced mountain groundwater recharge, even if total precipitation remains nearly the same, due to a potential increase in evapotranspiration associated with warmer temperatures. However, it is also possible that mountain recharge rates will remain unchanged or increase in response to climate change. For example, fractured-rock aquifers underlying mountain watersheds are typically permeability-limited rather than recharge-limited, so a reduction in snowmelt may have little influence on recharge rates (Earman 2012). Further, earlier snowmelt periods may cause more infiltration to occur early in the spring when evapotranspiration rates are low, leading to an increase in recharge. (Earman 2012.) As such, an assumption that climate change will result in reduced recharge and groundwater availability in the Project area is speculative and need not be analyzed in an EIR.

Nonetheless, Itasca performed an analysis of the impacts of changing recharge (to reflect changes in precipitation) on predicted inflows to the mine and the resulting impacts to drawdowns in shallow groundwater. These sensitivity scenarios (Scenarios 4 and 5) are discussed in Section 5.4 of Appendix K.3 of the DEIR. The results are that increasing or decreasing recharge by 50% (a very extreme case, that is beyond what can reasonably be expected) only changes the predicted inflows to the mine by +/- 3% compared to the base case. The small changes in

predicted inflows are due to the low *K*s of the deeper geologic units where the mining will occur. Higher recharge reduces the area of drawdown. If the recharge rate in the model domain is decreased by 50%, the extent of the 5-ft drawdown isopleth is larger than in the Base-Case Scenario, as decreased recharge impacts the shallow water-bearing zones more than the deep zone. The 5-ft drawdown isopleth is generally still within the mineral-rights boundary.

As shown on Figure 5-9 of Appendix K.3, the simulated 5-foot drawdown contour for Scenario 5 is very similar to the other sensitivity scenarios except for an expansion of the 5-ft drawdown to the south-east towards the greenhorn area by approximately 1500 feet. As further discussed on page 8 of Appendix K.3 of the DEIR, the consistent annual recharge may be due to the limitations of recharge in fractured bedrock, where the annual rainfall amount may be greater than the capacity of the fractures to accept additional flow. In this situation, increases or decreases in the annual rainfall due to climatic cycles do not have appreciable effects on the amount of water that can be recharged because the capacity of the fractures to transmit water in the subsurface is near its maximum. Thus, there may not be a substantial variation in recharge to the water-bearing geologic materials in the Project area. Nevertheless, the sensitivity of the model to changes in recharge has been evaluated, and even an extreme scenario of 50% recharge reduction, which is not expected to occur, did not significantly change the analysis.

The future effects of climate change on groundwater recharge are unknown due to the factors discussed above, and CEQA does not require the analysis of speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." As the impact of climate change on recharge is speculative, this impact need not be analyzed in an EIR.

However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the Project could result in a significant impact to groundwater supplies. An increase in drawdown caused by the Project due to reduced groundwater recharge combined with the Project dewatering would be detected in the required well monitoring and well mitigation plans. A Groundwater Monitoring Plan (GMP) is required for the Project under Mitigation Measure 4.8-2(a). Ongoing groundwater monitoring would be required, and groundwater-level information shall be obtained from the Project groundwater monitoring wells and collected on a quarterly basis and submitted in report form to Nevada County. Mitigation Measure 4.8-2(b) requires that if it is determined based on the GMP that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified.

## Water Balance - Groundwater and Surface Water Interaction

Several commenters assert that the water supply assessment and groundwater analysis in the DEIR is flawed and is based on inaccurate assumptions because it ignores the link between groundwater and surface water. However, the groundwater model and hydrologic analysis discuss in detail the linkage between surface water and groundwater, which is fundamental to the analysis. As shown in Figure 4-5 of Appendix K.3, the regional groundwater flows westerly past the Project site. The analysis determined that the groundwater that inflows into the mine workings originates from the entirety of the approximately 4,000 ft vertical thickness of the rock mass. The groundwater flow from the shallower rock unit to the mine workings could lower the water level of

the shallow groundwater system in the vicinity of the mining zone. However, the groundwater flow from the deeper rock units to the mine workings will not impact the shallow groundwater level. All the inflow to the mine workings will be pumped to surface, treated and discharged into South Fork Wolf Creek where it would then flow to Wolf Creek and then to the Bear River. As predicted in the groundwater flow model, the maximum reduction of the baseflow in Wolf Creek is approximately 0.85 cfs. The Project plans to discharge 1.9 cfs treated water to Wolf Creek. The Project produces water that has a beneficial use at surface (rather than flowing underground) but does not change the overall water balance.

As stated on page 2 of the Water Supply Assessment for the Project (Appendix N), the projected potable and non-potable water demand for building of the proposed project totals approximately 121 acre-feet per year. The Project is expected to be a net producer of water through its discharge of approximately 1,371 acre-feet per year of treated mine water to the South Fork of Wolf Creek. The Nevada Irrigation District (NID) could adjust its flows upstream to use the extra water available downstream if it desired to. As discussed on page 4.8-65 of the DEIR and page 25 of Appendix K.3, the groundwater model indicates that base flows in South Fork Wolf Creek and Wolf Creek would be reduced from mine dewatering by approximately 1 cfs, which is approximately 724 acre-feet per year, not counting the Project's addition of 1,371 acre-feet per year of treated mine water to the South Fork of Wolf Creek. Therefore, the net addition of water available for beneficial use on the surface is approximately 500 acre-feet/year. Portion of this additional water originates from the storage of the deeper rock units that have little hydraulic connection with the shallow groundwater system. As shown in Table 6-5 of Appendix N to the DEIR, a single dry year water supply for NID is estimated at 91,800 acre-feet per year. Although the quantity of water discharged from the proposed mine is small in comparison to the overall amount of NID water supply, the Project would provide additional water to NID customers during times of drought and therefore diversify water supplies available to the community and increase drought resiliency. This additional water would not likely influence measures of the NID Drought Plan (see Section 6.5 of the NID 2020 Urban Water Management Plan). However, it should be noted that stages 1 through 5 of the NID Drought Plan only impose restrictions to outdoor irrigation on treated water customers and stage 6 of the NID Drought plan maintains health and safety use of water for treated water customers. Therefore, properties in the E. Bennett area which are connected to NID water supply under the Project's Well Mitigation Plan (Appendix K.9) would be assured water delivery for necessary use by NID even during the most severe droughts. As discussed in Appendix K.9, property owners may also choose to retain and continue using their water wells in addition to the NID potable water if they desire.

## Conclusion

The future effects of climate change on groundwater recharge are unknown due to the factors discussed above, and CEQA does not require the analysis of speculative impacts (Section 15384). As the impact of climate change on recharge is speculative, this impact need not be analyzed in an EIR. Nevertheless, the DEIR includes an analysis of the effects of changing recharge (to reflect changes in precipitation) on predicted inflows to the mine and the resulting impacts to drawdowns in shallow groundwater. The results are that increasing or decreasing recharge by 50% (a very extreme case, that is beyond what can reasonably be expected) only changes the predicted inflows to the mine by +/- 3% compared to the base case. In addition, there is consistent annual recharge which may be due to the limitations of recharge in fractured bedrock, where the annual rainfall amount may be greater than the capacity of the fractures to accept additional flow. In this situation, increases or decreases in the annual rainfall due to climatic cycles do not have appreciable effects on the amount of water that can be recharged because the capacity of the fractures to transmit water in the subsurface is near its maximum. Therefore, while

speculative, climate change is not anticipated to significantly effect groundwater recharge, and the DEIR's groundwater analysis adequately evaluates the project's potential to substantially deplete groundwater supplies (Appendix G, X(b)).

## Master Response 17 - Meteorological Data Used in HRA

### Comments

Several commenters assert that the Health Risk Assessment (HRA) performed for the project did not use appropriate meteorological data for the Grass Valley Area.[9]

### Discussion

The dispersion model in the Health Risk Assessment used the most appropriate data for the analysis. AERMOD requires pre-processed met data, which is only available from specific sites. Dudek analyzed the available data compared to actual data at the closest weather station to the project site and Blue Canyon was most representative. There is no AERMOD pre-processed met data from Grass Valley or the Nevada County Airport.

As stated on page 12 of the Health Risk Assessment (Appendix E.1 of the EIR), the nearest stations with processed meteorological data for use in AERMOD are Blue Canyon (17 miles away), Auburn (18 miles away), and Beale (22 miles away). The predominant wind direction at the project site is from the North-East and South-West direction as shown in Figure 20 below[10]. The Blue Canyon met station has a predominant wind direction from the North-East and South (Figure 21); the Auburn met station from the East (Figure 22); and the Beale met station from the South-East and North-West[11] (Figure 23). Blue Canyon was selected since it is the closest station and is the most representative of the project site.

As stated on page 27 of the Health Risk Assessment (Appendix E.1 of the EIR), the maximally exposed receptor (MER) would be the nearest existing residence to the north of the Brunswick Industrial Site. The predominant wind direction used for dispersion modelling is from the south (see Figure 20 of the Health Risk Assessment). Project emissions from construction activities at the Brunswick Site, shaft, process plant, and truck traffic are generally to the south and in proximity to the MER. (see Figure 3.3 of the DEIR and/or the more detailed map that was also submitted with the Use Permit application)[12]. As such, with the predominant wind direction blowing directly towards the nearest sensitive receptor, the Health Risk Assessment for the project presented a conservative analysis.

Furthermore, Dudek contacted the Northern Sierra Air Quality Management District (NSAQMD) to discuss recommended meteorological stations for the Health Risk Assessment prior to

[9] The results of the HRA are incorporated into Chapter 4.3, Air Quality, Greenhouse Gas Emissions, and Energy, to address Appendix G, III(c) regarding whether the project would expose sensitive receptors to substantial pollutant concentrations.

[12] https://www.nevadacountyca.gov/DocumentCenter/View/30404/Brunswick-Site-Plan---Infrastructure

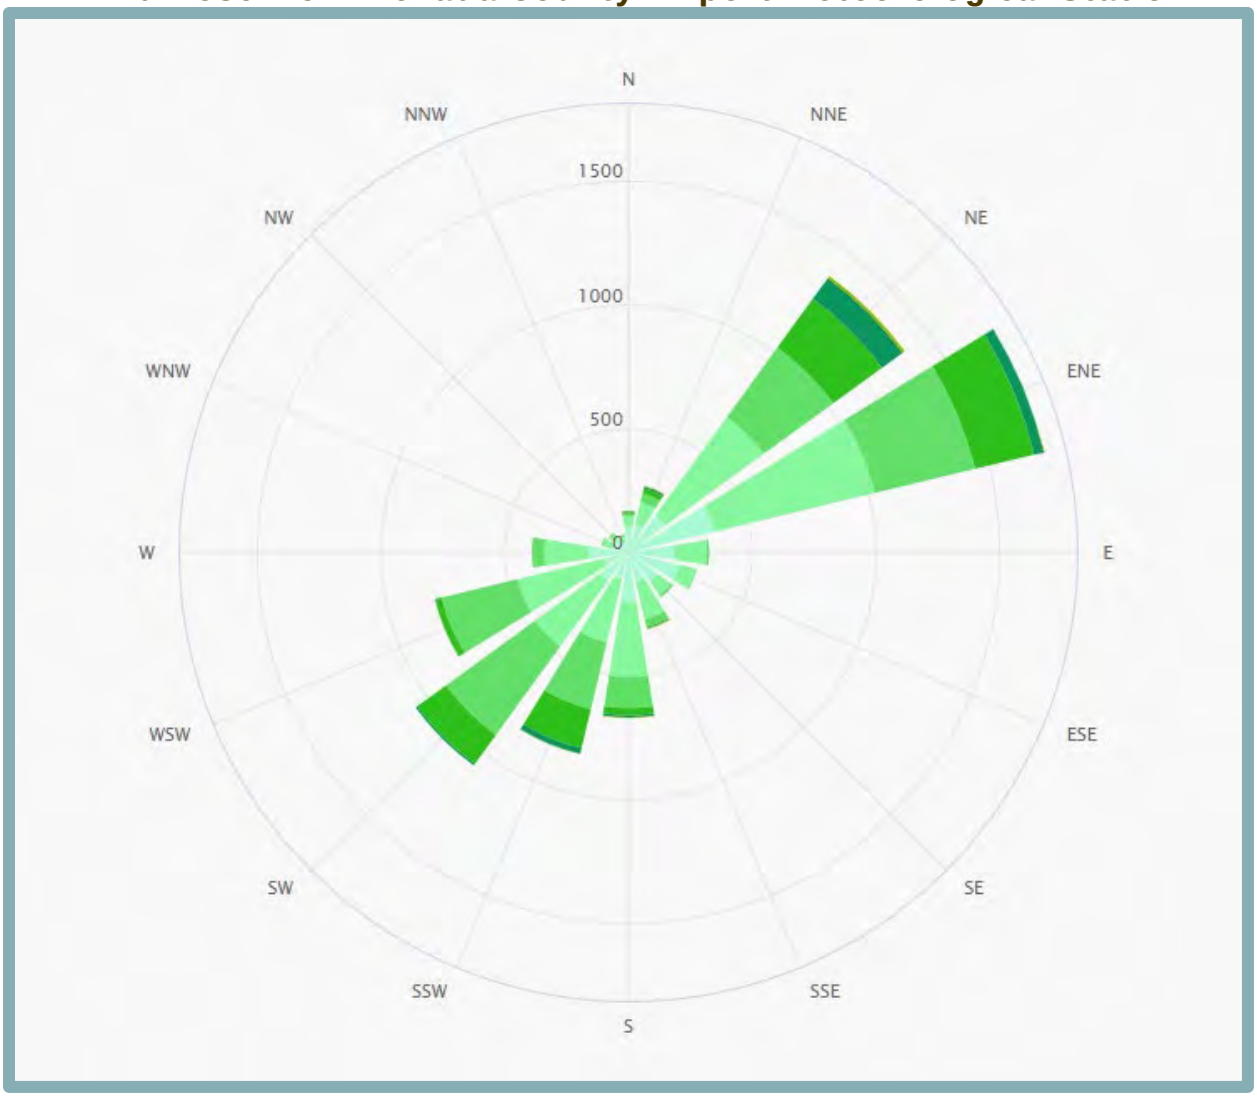
commencing the analysis; however, the NSAQMD did not provide a recommendation as to the most representative meteorological data for the project site. The NSAQMD reviewed the Health Risk Assessment four times (three times prior to public review of the DEIR, April 20, 2020, February 10, 2021, and June 4, 2021) and did not suggest using different meteorological data for the Health Risk Assessment. The NSAQMD is the air quality authority for the County and the project site and did not object to the use of the Blue Canyon meteorological station as representative of the meteorological conditions at the Project site.

### Conclusion

The use of meteorological data from the Blue Canyon area represents the best available processed data for use in the HRA and is adequate for purposes of CEQA.

## Master Response 18 - Air Quality Thresholds

### Comments



Several commenters have questioned the thresholds utilized in the DEIR to identify potential Project impacts associated with emissions of criteria pollutants and toxic air contaminants.

### Discussion

As stated on page 4.3-42 of the DEIR, use of the Northern Sierra Air Quality Management District's (NSAQMD) cancer and noncancer thresholds to assess health risk significance for CEQA is consistent with AB 2588 risk assessment procedures. The threshold of significance for health risk is an increased cancer risk of >10 cases per million persons and a hazard index of >1 for increased non-cancer risk. The Health Risk Assessment ("HRA") prepared for the Project concludes that the health risk to the most sensitive receptor will be below these thresholds. The threshold of significance for exposure to toxic air contaminants is based on an incremental increase in cancer and non-cancer risk associated with a project. As such, the baseline concentration does not factor into this impact determination.

Several commenters have stated that the American Lung Association gives Nevada County an "F" for ozone levels and therefore the threshold for the Project's emissions, as discussed in the DEIR, are not valid. Ozone is a reactive gas formed as a result of a complex chemical reaction between reactive organic gases (ROG) and oxides of Nitrogen ($NO_x$) in the presence of sunlight. As such, unlike other pollutants, ozone is not released directly into the atmosphere from any sources. The Project's emissions of ROG and $NO_x$ are considered criteria air pollutants. As discussed on page 4.3-41 of the DEIR, the NSAQMD established thresholds of significance for criteria air pollutants for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because AAQS are based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse effects to human health related to criteria pollutant emissions. Therefore, the NSAQMD thresholds are the correct thresholds.

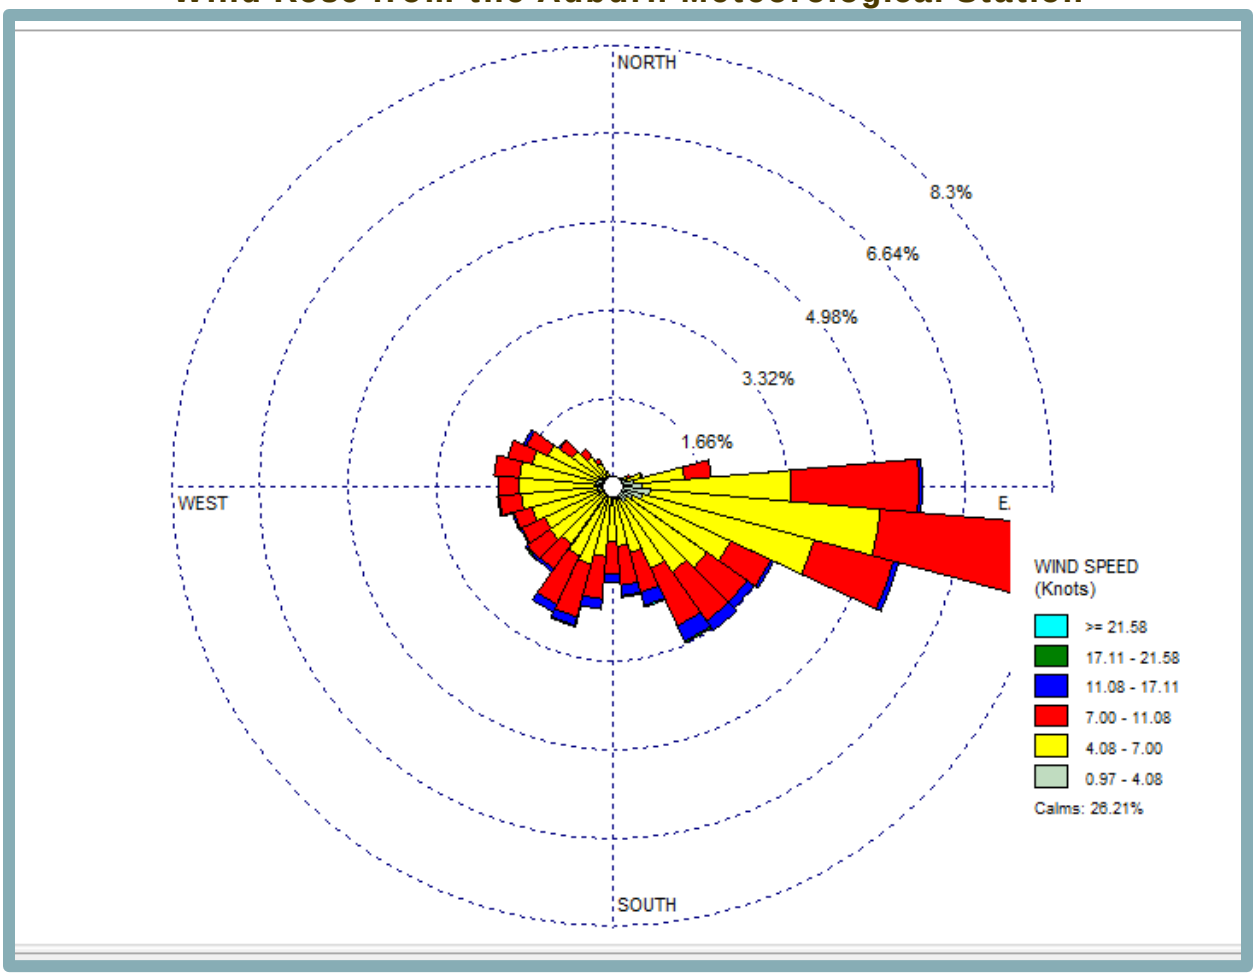
**Wind Rose from the Auburn Meteorological Station**



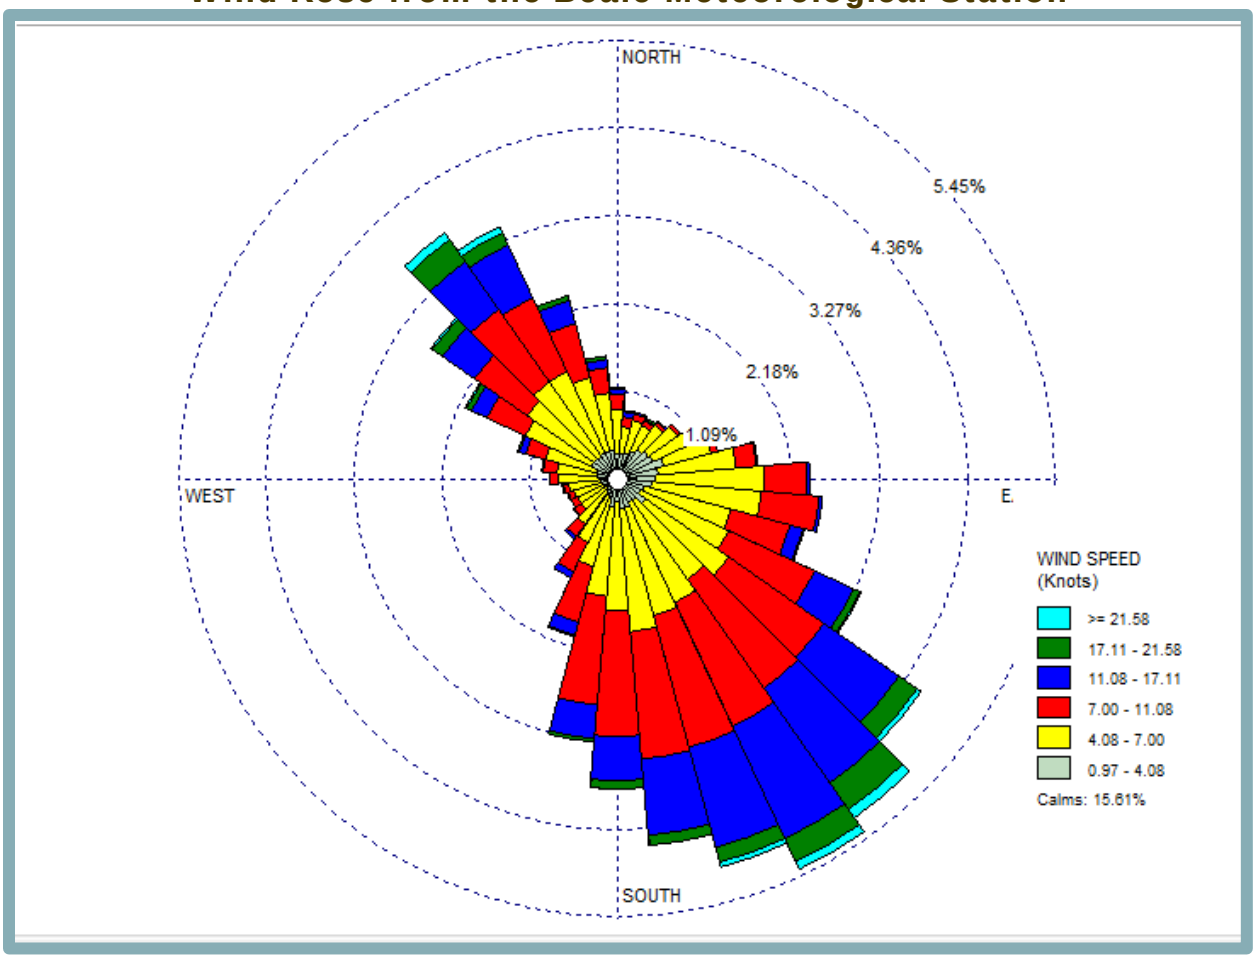


**Figure 23**
**Wind Rose from the Beale Meteorological Station**

Several commenters request that the demographics of the community, including age and specific illness rates be considered in the health risk analysis. Health risk assessments do not account for County-specific illness rates. However, as discussed in Section 2.1 of the HRA for the Project, implementing the State OEHHA Guidance, as was done for the Project, reflects conservative, health-protective methodologies to assess health impacts to adults, as well as infants, children, and other sensitive subpopulations. For example, the reference exposure levels (RELs) used in the evaluation of non-cancer risk are designed to protect the most sensitive individuals in the population, including infants and children, by selecting appropriate toxicological data and including margins of safety. Accordingly, the evaluation methods are assumed to protect children and other sensitive subpopulations (groups of more highly susceptible individuals) from adverse health effects in the event of exposure. A similar approach was taken for cancer risk, which accounts for the higher sensitivity of infants and children by applying age-specific daily breathing rates and age-sensitivity factors (ASFs), as well as conservative exposure period, fraction of time at home, and cancer potency factors as recommended by OEHHA. Less sensitive receptors, including facilities at a further distance than receptors around the sites, would have less exposure and consequently less potential health risk than the MEIR. Therefore, the HRA used State Mandated Guidance.

The HRA prepared for the Project uses a 30-year exposure timeframe, and several commenters have asked what health impacts will occur after that 30-year period. As stated on page 26 of the HRA (Appendix E.1 of the DEIR), OEHHA describes cancer risk evaluations for 9-, 30-, and 70-year exposure durations in the 2015 OEHHA Guidelines and identifies that the 9- and 30-year durations correspond to the average and high-end of residency time recommended by the EPA, with the 30-year exposure duration recommended for use as the basis for estimating cancer risk at the maximally exposed individual resident in all HRAs. OEHHA recommends that a 30-year exposure duration be used as the basis for estimating cancer risk at the maximum exposed individual resident (MEIR) in the Hot Spots Program. This exposure duration represents the time of residency for 90 to 95% of Californians at a single location and should provide adequate public health protection against individual risk. (Section 8.1 OEHHA 2015 Air Toxics Hot Spots Program Manual). As standard practice, the duration of exposure is based on 30-year sensitive receptor residency rather than the life of a project.

### Conclusion

This master response demonstrates that the thresholds used in the DEIR to identify potential project impacts associated with emissions of criteria pollutants and toxic air contaminants are consistent with the local air district's (NSAQMD) guidance and protective of human health.

## Master Response 19 - NSAQMD Criteria Pollutant Thresholds During Operations

### Comments

Several commenters asserted that mitigation is not incorporated for criteria air pollutants for the operational phase of the Project.

### Discussion

Contrary to the comments, the Project incorporates the mandatory mitigation of criteria pollutants required by the Northern Sierra Air Quality Management District (NSAQMD) in both construction and operations. Moreover, the Project incorporates applicant proposed measures (APMs) that serve to reduce project emissions of criteria air pollutants (DEIR, p. 4.3-65). The APMs will be mandatory conditions of approval and included in the mitigation monitoring and reporting program.

As an example, the project includes the use of Tier4F engines to reduce emissions, which is not a mandatory measure required by NSAQMD. Tier 4F standards require that emissions of PM and NOx be reduced by about 90% versus Tier 1-3 standards[13]. The use of Tier 4F engines reduces the project's emissions of criteria air pollutants and decreases health risk from the project through the reduction of diesel particulate emissions.

As discussed on page 4.3-41 of the DEIR, Appendix G of the CEQA Guidelines (14 CCR 15000 et seq.) indicates that, where available, the significance criteria established by the applicable air quality management district or air pollution control district may be relied upon to determine whether the project would have a significant impact on air quality.

The NSAQMD has developed a tiered approach to significance levels. The tiered thresholds for Levels A, B, and C are applicable for a particular project based on that project's estimated emissions of criteria pollutants in pounds per day. A project with emissions qualifying for Level A thresholds (i.e., all projects with emissions greater than zero, but less than level B requires the most basic mitigation. Projects that qualify for Level B require more extensive mitigation, and projects that qualify for Level C require the most extensive application of mitigation.

Mitigation Measure 4.3-1(a) requires the mitigation measures identified in the NSAQMD's *Guidelines for Assessing and Mitigating Air Quality Impacts of Land Use Projects* for significance levels A and B thresholds during project construction. However, these measures are already addressed in the design during operations (Year 2022 and later), as follows:

1) The project would not burn vegetative material. Processing of vegetation before placement of engineered fill would be done by chipping.
2) Grid power is already used to the maximum extent feasible. The entire underground mine and process plant are powered by electricity.
3) No temporary traffic control is needed during operations.
4) The employee work schedule is designed to result in the majority of employee traffic to occur during off-peak hours (268 of 312 employees – see Table 3-8 of the DEIR)

Burning of vegetative material will be prohibited in a condition of approval, which is included in the Mitigation Monitoring and Reporting Program (MMRP) (Chapter 4 of this Final EIR). In addition to the mandatory mitigations required by the NSAQMD, the project proposes to utilize Tier4F engines for offroad equipment.

## Utilize Tier 4F Engines

During construction, the off-road equipment used will likely be owned by contractors who may or may not utilize equipment with Tier 4 Final engines. The unmitigated emissions presented in the Air Quality Analysis of the DEIR assumes the use of lower tier equipment. Mitigation Measure 4-3-1(b) requires a Construction Exhaust Emissions Minimization Plan and the use of Tier 4 Final engines or alternative sources of power. The mitigated emissions presented in the Air Quality Analysis of the DEIR reflect the lower emissions that would be achieved by this mitigation measure.

During operations, the off-road surface equipment used will be owned or contracted to the applicant. This equipment is specified to have Tier4F engines (see page 131 of pdf Appendix E.1). All underground equipment will be powered by electricity. Therefore, for the years after construction (2022-2026, 2027-2032, 2033-2102, and 2103) the unmitigated and mitigated emissions presented in the Air Quality Analysis of the DEIR are identical. The use of electric and

[13] https://www.transportpolicy.net/standard/us-nonroad-emissions/

Tier4F engines diesel engines has been incorporated into the design of the project during operations and therefore a mitigation measure for their use during operations is not required in the DEIR.

The NSAQMD recommended mitigation measures are incorporated in the Project design. The applicant has included multiple APMs in order to reduce the level of emissions as part of the project design, which will be conditions of approval for the project, and which are included in the MMRP. Chapter 4 of the FEIR, Mitigation Monitoring and Reporting Program, includes these APMs. These APMs, which go above and beyond the measures suggested in the NSAQMD *Guidelines for Assessing and Mitigating Air Quality Impacts of Land Use Projects* (such as Tier4F surface equipment and all electric equipment underground) were already incorporated into the assessment and, therefore, do not result in additional reductions under the mitigated scenario, nonetheless the APMs do reduce emissions of criteria air pollutants compared to the Project if it did not incorporate these emission reducing features. With these APMs and mitigations applied to the project, criteria air pollutant emissions levels would not be above the NSAQMD threshold level C, and therefore, the project would not result in significant emissions of criteria air pollutants. Notably, the DEIR's application of the NSAQMD CEQA thresholds is consistent with Nevada County's use of these thresholds for other Projects in the County, such as the Lake Wildwood Tennis Facility Lighting Expansion Project, the Auburn Ski Club Project, and the Rincon Del Rio Project, for which use of the mandatory NSAQMD mitigation is deemed to reduce emissions of criteria pollutants (at a NSAQMD A or B threshold level) below a level of significance.[14]

### Conclusion

The Project requires the mandatory NSAQMD mitigation but also goes beyond that with the APMs; as such, the DEIR appropriately deems the Project's impact associated with emissions of criteria pollutants as less than significant after implementation of mitigation (DEIR, p. 4.3-73).

## Master Response 20 - Conservatism of Metals Assumptions

### Comments

The County received several comments asserting that the Health Risk Assessment (HRA) underestimated health impacts from metal content in fugitive dust. Consequently, these commenters requested that the HRA be revised.

### Discussion

The HRA (included in Appendix B of Appendix E.1 of the DEIR) considered the metal content of fugitive dust emitted by the project activities in determining the potential health risk of the project. Arsenic, beryllium, cadmium, copper, lead, manganese, mercury, nickel, selenium, and vanadium have approved risk assessment health values for use in the Assembly Bill (AB) 2588 Air Toxics "Hot Spots" Program and the health risk from these metals are therefore included in the HRA for the project. Arsenic, beryllium, cadmium, lead, and nickel have cancer potency factors, while copper, manganese, mercury, vanadium, and selenium have acute and/or chronic relative exposure levels (RELs).

The HRA for the project assumes metal proportions for mined materials from exploration sampling presented in Section X of the Hydrology Report (Appendix K.2 of the DEIR) in order to analyze

[14] https://www.nevadacountyca.gov/DocumentCenter/View/44636/Lake-Wildwood-Tennis-Facility-Lights-Notice-of-Availability-and-Initial-Study-PLN22-0008-AAP22-0001-VAR22-0004-EIS22-0008-, pp. 14-15; https://www.nevadacountyca.gov/DocumentCenter/View/44519/Auburn-Ski-Club-Notice-of-Availability-and-Initial-Study-PLN22-0092-AAP22-0002-EIS22-0007-VAR22-0003, pp. 16-18; https://www.nevadacountyca.gov/DocumentCenter/View/12692/33-Air-Quality-Draft-PDF, p. 3.3-20-23.

the health risk from fugitive dust. These specific assumptions are provided in Appendix B of Appendix E.1. For conservatism, the metal values of the altered meta-andesite sample, which had the highest toxic metal content of any mineral type sampled from the project site, were used to represent the metal content of all barren and mineralized rock in the underground mine. This sample has significantly increased arsenic (35 parts per million [ppm]) and lead (23 ppm) versus the barren rock composited samples with 3 ppm arsenic and 3 ppm lead, and to a lesser extent, increased cadmium (0.35 ppm versus 0.34 ppm). As a consequence, the HRA conservatively assumes that all materials, including the 500 tons per day of barren rock mined (which generally has much lower metal content), have the same metal content as the meta-andesite sample for purposes modeling dust emissions from the underground mine. This approach overstates the metal content of the average rock mined at the project site to provide a conservative analysis of impacts.

The same approach was taken for the mineral process plant where all rock and sand tailings were assigned with the higher mineralized metal values from the meta-andesite sample rather than the values of the unmineralized barren rock and sand tailings (sulphide minerals containing metals will have been removed from sand tailings). Engineered Fill is composed of 50 percent barren rock and 50 percent sand tailings. The metal values for these materials were averaged and then doubled to include conservatism for dust emissions from the placement and compaction of engineered fill. Dust emissions from the moving of soil were also assigned the same values.

The HRA for the project also makes the conservative assumption that all metals are 100 percent bioavailable. Cancer potency factors are based on metallic metals; however, the metals in rock dust are in mineral forms such pyrite ($FeS_2$), arsenopyrite (FeAsS) and galena (PbS), which do not have 100 percent bioavailability. The California Department of Toxics Substances Control (DTSC) has conducted research into the bioavailability of arsenic in historic Empire Gold Mine materials and concluded that using the customary default of 100 percent relative bioavailability leads to an overestimation of risk. The bioavailability ranged depending on the sample and method of determination with mean bioavailability ranging up to 15.9 percent. (DTSC 2015 p. 8, Table 2).

### Conclusion

Given that the overall metal content in the rock to be mined at the project site is based on the high-metal-content altered meta-andesite sample and is therefore likely overstated, and that the assumed 100 percent bioavailability of the metals is also a likely exaggerated, the HRA provides a conservative analysis of health impacts from metal content in fugitive dust. As such, the commenters' requested revision to the Health Risk assessment is not required, because the DEIR adequately analyzed the impacts and properly relied on conservative assumptions.

## Master Response 21 - Conservatism of Silica Assumptions

### Comments

Several commenters raised concerns regarding health risks associated with silica exposure, asserted that the Health Risk Assessment (HRA) underestimated health risk from silica exposure, and requested additional sampling of rock for silica content and revision to the HRA.

## Discussion

As explained below, the HRA used numerous conservative assumptions at every stage in the analysis, which together tend to overstate rather than underestimate the likely health impacts from silica exposure. Therefore, the DEIR properly analyzed health impacts from silica exposure and concluded that health risks as a result of the project would be less than significant after implementation of mitigation (DEIR, p. 4.3-82).

The Office of Environmental Health Hazard Assessment (OEHHA) adopted a chronic Reference Exposure Level (REL) for silica (crystalline, respirable) on February 10th 2005. (see https://oehha.ca.gov/air/document/adoption-chronic-reference-exposure-levels-silica-crystalline-respirable .) A chronic REL is an airborne level of a chemical at or below which no adverse health effects are anticipated in individuals indefinitely exposed to that level. (Id.) The chronic REL for silica is 3 micrograms per cubic meter ($\mu g/m^3$). (OEHHA Chronic Toxicity Summary, Silica, p. 1.) No acute REL has been established for crystalline silica. (Id.)

The REL for silica is meant to be applied only to particles of crystalline silica (quartz, cristobalite, tridymite) of respirable size which has a 50 percent cut-point at 4 micrometer (um) particle aerodynamic diameter. This occupational definition of "respirable" differs from the environmental definition of "respirable," which is known as $PM_{10}$ (particles of 10-micron diameter or less) (OEHHA Chronic Toxicity Summary, Silica, p. 1).

The emission of dust from the project was modeled in the HRA (included in Appendix B of Appendix E.1 of the DEIR) as $PM_{10,}$ and the health risk analysis used a conservative assumption that 60 percent of $PM_{10}$ is respirable crystalline silica for the purpose of quantifying silica exposure to receptors. This is useful as a screening method because if the silica concentration in $PM_{10}$ modeled at a receptor is less than the REL (3 $\mu g/m^3$), respirable silica (50 percent cut-point at 4 micrometer (um) particle aerodynamic diameter) will also be less than 3 $\mu g/m^3$, so a project would not pose a risk due to silica at that receptor. However, the use of $PM_{10}$ overestimates the relevant exposure in any situation, as it includes silica particles that would not be considered "respirable" under the OEHHA definition. (OEHHA Chronic Toxicity Summary, Silica, p. 37)

As stated above, the HRA for the project assumes a generalized 60 percent silica content for all dust, and assumes all this silica is crystalline quartz, to calculate exposure of receptors to silica, which is a conservative assumption. Quartz (crystalline silica) is composed of silica ($SiO_2$). Silica is also found in the amorphous (non-crystalline) state. The majority of barren rock that will be mined by the proposed project is metamorphosed andesite (meta-andesite). Andesite contains less than 20 percent quartz and averages approximately 6 percent quartz (Mindat.org n.d.). Quartz can be a product of metamorphism due to crystallization from silica bearing fluids (IARC 1997 p. 60). The presence of quartz phenocryst in the meta-andesite "porphyrite" of the Brunswick area is reported by the United States Geological Survey (USGS) (W.D. Johnston Jr 1940 p. 10). Gold is hosted in discrete veins and in stockworks consisting primarily of massive to banded, sheared, and brecciated milky white quartz plus or minus carbonate. The historic veins mined in the Idaho systems averaged from 3 feet to 5 feet. Veins in the Brunswick mine generally ranged from inches to 7 feet or developed in stockwork zones of quartz stringers (AMEC 2017 Section 7.4). Gold mineralization which is mined therefore is not composed entirely of quartz but includes other minerals. Gold mineralization is also diluted during mining by the rock surrounding the veins as full recovery of the vein is desired and mining width requires mine excavations to be of a minimum width. The minimum mining width is dependent on the mining equipment and method used but would not be less than 6 feet. Therefore, a typical "solid" quartz vein would be diluted by one ton of other minerals for every ton of quartz rock.

The HRA model assumed that mined mineralization contains 80 percent quartz (1,000 tons per day) and barren rock contains 20 percent quartz (500 tons per day), which results in an average quartz content of 60 percent for all mined materials. As explained above, the 60 percent quartz content is higher than what is actually expected. Engineered fill produced by the project would be composed of 500 tons barren rock and 500 tons sand tailings. The above assumptions of quartz content would result in an average quartz content of 50 percent for engineered fill; however, the HRA assumed a higher quartz content of 60 percent.

Further evidence of conservatism in the HRA is provided by dust sampling at active mines by inspectors in the United States from 1988-1992. Mean quartz content of 238 samples in underground gold mines was 9.0 percent and from 334 samples at gold mills was 15.3 percent (IARC 1997 p. 66, Table 12). Accordingly, the assumption of 60 percent quartz content is significantly larger than measured values in producing gold mines and process plants, and likely overstates the actual amount of quartz (and therefore crystalline silica) that will be mined by the project.

### Conclusion

Given that the HRA assumes a greater crystalline silica content in the mined rock than is likely or observed in similar mines, and also uses an overinclusive definition of "respirable" silica particle size by counting all silica particles of a diameter of 10 microns or less, the HRA overestimates health impacts from respirable crystalline silica exposure. Accordingly, the commenters' requested additional sampling of materials for crystalline silica content or revision to the HRA is not required. because the DEIR properly analyzed the impacts of silica.

## Master Response 22 - Conservatism of Asbestos Assumptions

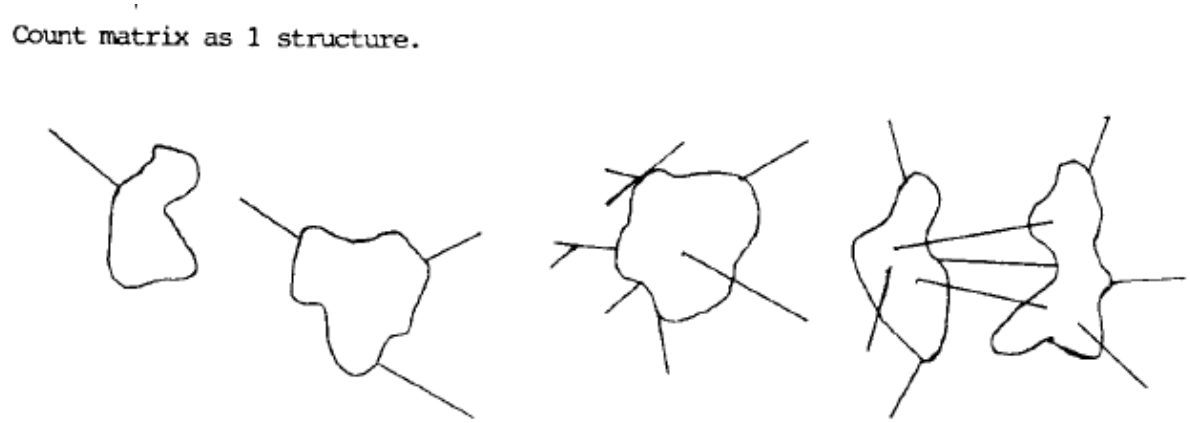
### Comments

Several commenters asserted that the assumptions used in the Health Risk Assessment (HRA) understated the amount of asbestos that will be found in the rock mined at the project, and likewise the level of respirable asbestos that will be emitted into the air. Conversely, the assumptions used for the HRA were based on conservative assumptions that overstate the amount of asbestos in

the rock and tailings and overstate the amount of asbestos that will become airborne. As such, the HRA provides a conservative analysis of asbestos impacts, and thus, adequately evaluates the potential health effects from asbestos attributable to the proposed project.

## Discussion

The HRA for the Project (included in Appendix B of Appendix E.1 of the DEIR) assumes that all rock mined will contain 1.07 transmission electron microscopy (TEM) asbestos structures per nanogram (s/ng) (0.01 percent phase contrast microscopy [PCM] equivalent weight percent). This is a conservative assumption based on the asbestos testing conducted on exploration samples presented in the Asbestos, Serpentinite, and Ultramafic Rock Management Plan (ASUR Plan) (Appendix E.2 of the DEIR). The majority of the 500 tons per day of barren rock produced by the Project is expected to be composed of meta-andesite. Exploration sampling shows this lithology averages 0.26 TEM structures per nanogram (Appendix C of the ASUR Plan). The assumed asbestos content for barren rock used in the HRA for the Project is approximately 4 times the sampled values; thus, the HRA analysis already includes a conservative 4x factor overestimation of asbestos content in barren rock.



The Project would produce 1,000 tons per day of sand tailings. The applicant submitted two samples of the historical tailings for TEM asbestos testing, which are presented in Appendix C of the ASUR Plan (Appendix E.2 of the DEIR). One sample of historic tailings did not contain any asbestos and one sample contained 0.03 TEM s/ng. In addition, NV5 submitted 10 samples retained from the historical tailings for TEM asbestos testing. Asbestos structures were not present in 7 samples from the western tailings area. Three samples from the eastern tailings area had detectable asbestos ranging from 0.081 s/ng to 0.214 s/ng (see Master Response 9 – Historical Mine Waste at Centennial Site). The average asbestos content of the 10 samples of historic tailings collected by NV5 was 0.049 TEMS asbestos structures per nanogram. The assumed asbestos content for sand tailings used in the HRA for the project (1.07 TEM asbestos structures per nanogram) is over 20 times greater than the average content of the 10 samples taken by NV5 from the historic tailings area on the Centennial Site. As such, the HRA was modeled using asbestos content for the sand tailings that is much higher than is likely to be present during the life of the Project.

Air monitoring requirements will be specified in the approved Asbestos Dust Mitigation Plan (ADMP), which must be approved by the Northern Sierra Air Quality Management District prior to Project operations. The ADMP is required under the Asbestos Airborne Toxic Control Measure (ATCM) for Construction, Grading, Quarrying, and Surface Mine Operations. Section (h)(3) of the ATCM specifies the requirement for analysis of air samples. Analysis of all air samples shall follow the analytical method specified by the United States Environmental Protection Agency (USEPA) Asbestos Hazard Emergency Response Act (AHERA) criteria for asbestos (40 CFR, Part 763 Subpart E, Appendix A, adopted October 30, 1987). The ATCM modifies the AHERA criteria for asbestos and requires a lower detection limit and the counting of all asbestos structures irrespective of length, as per the following exceptions:

A) The analytical sensitivity shall be 0.001 structure per cubic centimeter (0.001 s/cc); and
B) All asbestos structure with an aspect ration greater than three to one (3 to 1) shall be counted irrespective of length.

The ATCM otherwise uses the AHERA criteria for asbestos. AHERA Recording Rules specify that a “matrix” is defined as a structure or structures with one end free and the other end is embedded in or hidden in a particle. A matrix where many asbestos structures are embedded in a dust

particle would be only counted as 1 structure. (see page number 789 on 40 CFR, Part 763 Subpart E, Appendix A)

Under the AHERA Recording Rules, if a fiber does not protrude with an aspect ratio of <3:1 then none of the embedded structures would be counted. (see page number 789 on 40 CFR, Part 763 Subpart E, Appendix A – Note that California uses a 3:1 aspect ratio as discussed above)

## Conclusion

The HRA for the project assumes that every asbestos structure present in dust (coarse particulate matter, $PM_{10}$) is liberated and would be counted as 1 structure in a given airmass. This is a very conservative assumption as a large proportion of asbestos structures in dust particles would not be counted as asbestos in air samples and therefore would not contribute to health risk from asbestos. As such, the HRA provides a conservative analysis of asbestos impacts, and thus, adequately evaluates the potential health effects from asbestos attributable to the proposed project.

## Master Response 23 - Adequacy of Sampling - Asbestos

## Comments

Several commenters have expressed concerns about the adequacy of asbestos sampling of geological materials conducted for the Idaho-Maryland Mine Project. Many commenters assert that the amount of rock sampled was insufficient for purposes of determining concentration of asbestos and associated risks of exposure.

## Discussion

As stated on page 7 of the Asbestos, Serpentinite, and Ultramafic Rock (ASUR) Management Plan attached to the DEIR, Rise completed 19 exploration drill holes, totalling 67,500 feet of drilling, from 2017 to 2019. Forty-two (42) samples, mainly from diamond drill core from various lithologies at the Idaho-Maryland Mine Project, were submitted for asbestos testing in 2019. PLM testing was done on forty samples and TEM testing was done on two samples. In 2021, Rise requested the 40 samples previously submitted (and analyzed by PLM) to be reanalyzed using the TEM method. Grouping by lithology is important as mining is planned and completed in the distinct geological units present in the mine. For example, serpentine is a lithology of concern due to the presence of chrysotile asbestos.

Several commenters have asserted that the applicant stopped exploration drilling when asbestos was detected. Drilling was stopped when the exploration geologist determined there was little potential for discovery of gold mineralization. Serpentinite is a poor host rock for gold mineralization and holes which encounter it are not continued in this lithology. Continued drilling, and sampling in geological units that have low potential for gold mineralization, would not be representative of the rock that will be encountered during mining operations. Asbestos sampling is not done at the same time as drilling and cannot be detected visually at the low levels present without sophisticated microscopy. Samples from various lithologies at the Idaho-Maryland Mine Project were selected for asbestos testing. The volume and methodology for sampling from the mine area is adequate for the intended purpose of supporting the thresholds and assumptions used in the ASUR Plan and HRA attached to the DEIR (see Master Response 22 – Conservatism Used for Asbestos Assessment). Samples were taken from geological units of the type where gold mining is expected to occur. The sampling methods requested by some commenters with more samples being taken from serpentine rocks and at greater depths than the gold mineralization would be inappropriate for the purpose of estimating asbestos from the planned mining operation, as these samples would not be representative of rock that would be encountered during gold mining activities.

Prior to underground gold mining, intensive planning efforts will be conducted as required under the ASUR Plan and as required to meet state and federal regulations and achieve safety, environmental, and economic goals. Please see Section 6.0 of the ASUR Plan (Appendix E.2 of the DEIR). Underground mine planning, as required in the ASUR Plan, includes exploratory drilling, geologic mapping, material logging, and testing. These same processes also ensure future mining operations avoid and manage rock types that may contain naturally occurring asbestos to ensure that applicable thresholds are not exceeded. In other words, the mandatory mine planning that is required by the DEIR in the ASUR Plan will provide information to the mine operator on asbestos content of rock prior to mining that area. This is a standard component of modern underground mine planning, and was made an explicit requirement of the ASUR Plan, which will be required through a Condition of Approval. As such, the ASUR Plan will be binding on the mine operator and any potential successors in interest to the mine.

Additionally, the HRA is based on conservative assumptions, such that the analysis overestimates health impacts rather than underestimates those impacts. Please see Master Response 22 – Conservatism Used for Asbestos Assessment.

## Conclusion

Based on these conservative assumptions, the DEIR concludes that the Project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to

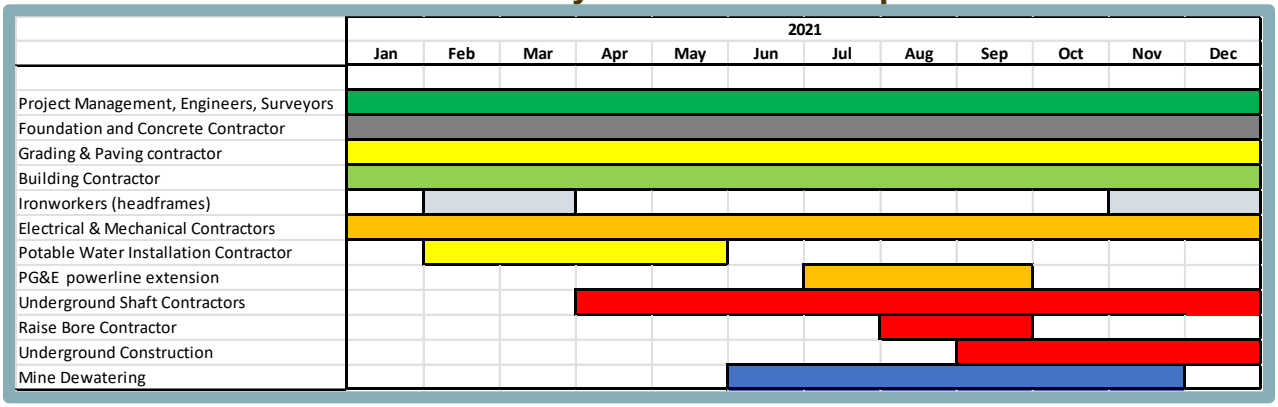
Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in Mitigation Measure 4.3-2. Additional measures, such as air monitoring, if required by the NSAQMD, would be detailed in the ADMP.

## Master Response 24 - Project Construction Schedule

### Comments

The County received several comments questioning the construction schedule presented in the DEIR. The primary concerns relate to the different construction timelines provided in the air quality (4.3) and project description (3.0) chapters of the DEIR, and the assertion that all phases of construction cannot fit within either timeline. In general, no specific conclusions are drawn from these comments, but rather, the assertion is made that the DEIR analysis would result in different impact conclusions had the construction timeline been more accurate.

### Discussion



As discussed below, the DEIR assumed an aggressive construction schedule where many activities are overlapping or occurring simultaneously, to provide a conservative assessment of construction noise and air quality impacts. The actual construction schedule may occur as presented in the DEIR, or may be spread out over more time, which would reduce impacts.

Table 3-7 of the DEIR estimates 18 months for aboveground facility construction and 6 months for initial mine dewatering and notes that durations are approximate and dependent on factors such as equipment and personnel availability, fluctuations in the economy, and technical details.

Certain activities must happen sequentially while others may be done in parallel. For example, on page 3-40 of the DEIR, the use of NID supplied water for dust suppression in construction grading is assumed until the mine water treatment plant becomes operational. During this time, the NID potable water line could also be under construction, which is estimated to take four months to complete (page 4.10-27 of the DEIR).

As described on page 4.3-44 of the DEIR, the air quality assessment assumed in general, construction was anticipated to occur over approximately 12 months. The various construction tasks required for the Project and the related equipment emissions were modelled in sequence on a monthly basis as detailed on pages 123 through 127 of Appendix E.1 of the DEIR and shown in Figure 24 below.

**Figure 24**
**Construction schedule assumed in Air Quality and Greenhouse Gas Emissions Analysis Technical Report**

The construction scenario assessed in the air quality analysis is the worst-case, because if the same construction activities were to be spread over a longer period (i.e., a period in excess of 12 months), the amount of overlap of equipment usage would be reduced, which would result in reduced maximum daily and annual emissions. Lengthening the construction period would also push out the operational and reclamation phases by the same amount of time. The actual construction period would depend on numerous factors including permitting timelines and economic conditions.

### Conclusion

In general, an increase in the duration of construction activities and/or the completion of activities sequentially would serve to reduce environmental impacts in many areas, such as air quality and noise due to the reasonably assumed smaller vehicle/equipment fleet that would be required to complete concurrent construction of more than one phase. The conservative approach, which has been taken in the DEIR, is to assume a more aggressive construction timeline. This approach is adequate pursuant to CEQA.

## Master Response 25 - Nevada County Energy Action Plan

### Comments

Several commenters asserted that the Project is not consistent with the County Energy Action Plan (EAP). As set forth below, the Project furthers some of the strategies outlined in the EAP, and supports the voluntary goals of the EAP, as required by App. G, Section VI(b).

### Discussion

As stated on page 4.3-89 of the EIR, Nevada County adopted the EAP in 2019. The EAP includes voluntary actions that are intended to meet the goals of reducing Countywide annual electricity demand by 51 percent and natural gas consumption by 30 percent in the year 2035, relative to a year 2005 baseline. The EAP is not a Qualified GHG Emissions Reduction Plan under CEQA pursuant to the requirements outlined in the CEQA Guidelines, Section 15183.5(b); therefore, no subsequent CEQA document can tier from the County EAP and the Project DEIR did not attempt to do so. In addition, the EAP is not a GHG reduction plan and does not provide carbon emissions inventory or strategies for the reduction of GHG emissions in the County other than those associated with the use of utility supplied electricity and natural gas. The reduction of GHG emissions from the reduction of electricity are not quantified in the EAP. The EAP does not consider the use of propane or other fossil fuels, electrification of vehicles, or retrofitting of homes heated by fossil fuels. Once again, the DEIR did not attempt to use the EAP for those purposes. Nevertheless, the compliance of the Project with EAP strategies has been analyzed and the Project found to be consistent with the EAP; therefore, the Project does comply with Section VI(b) of the Appendix G of the CEQA Guidelines because the Project is consistent with the EAP.

The EAP was prepared by the Sierra Business Council and accepted by the Board of Supervisors on February 12, 2019. The EAP provided an analysis of the energy use within the unincorporated County limits by the community and County operated facilities. (see page 1 of the EAP).

The actions within the EAP are voluntary and do not require the County or community to meet the reduction goals. The goal of the plan is to reduce energy use through efficiency, which would save utility customers money, energy, and water (see page 2 of EAP). The EAP sets a goal of reducing electricity use by 51 percent from the Business-as-Usual projection for the year 2035. The majority of savings are attributed to encouraging the installation of renewable energy on existing and new homes and persuading residents to reduce energy use. The potential energy reduction calculations are provided in Appendix C of the EAP and summarized as follows.

| | Strategy | Assumption | Projected Electricity Savings (GWhr) |
|---|---|---|---|
| 1.1 | Outreach and education on energy efficiency practices, programs, and financing options for utility customers. | Projection that 50% of customers will be persuaded to reduce energy use by 30% | 51.0 |
| 1.2 | Improve compliance with current California Building Energy Efficiency Standards (Title 24, part 6) by providing information materials. | 100% of new construction meets Title 24 standards | 6.5 |
| 1.3 | Improve energy efficiency of County buildings, facilities, and operations | Reduce energy use in County buildings and public lighting by 50%. | 2.6 |
| 2.1 | Encourage inclusion of renewable energy systems in new construction and large retrofit projects by providing informational materials when available. | 100% of new development meet required zero-net-energy standards by 2035 | 24.0 |
| 2.2 | Encourage renewable energy projects through education, outreach, and local leadership | 7,946 solar participants (56 MW installed power) and 4,099 wind participants (90' Rotor Hub) | 112.5 |
| 3.1 | Improve outreach and education in collaboration with NID by providing information on existing and future programs | 100% of households and Businesses reduce indoor water use by 50% | 1.6 |
| 3.2 | Encourage utilities district to reduce water losses through leak detection programs | Reduce water losses by 50% | 0.1 |
| 3.3 | Improve efficiency of County Wastewater Treatment and encourage other agencies to improve efficiency | Reduce energy intensity of wastewater treatment by 30% | 0.7 |
| | **TOTAL** | | **199.0** |

The new structures proposed by the Project will all meet Title 24 standards in applicable buildings, which is consistent with the EAP. (see DEIR Table 4.3-22.) Further, Project activities would comply with water efficiency Title 24, Part 11 (CALGreen Code) standards in applicable buildings, including installing toilets, urinals, faucets, and showerheads subject to the CALGreen maximum flow rates, which is consistent with the EAP water saving goals. (Id.) While solar panels are not now proposed as part of the Project, the roof space of the Project buildings may be available in the future for installation of solar panels to reduce the Project's reliance on the energy grid. Moreover, the proposed project does not otherwise interfere with the strategies proposed by the EAP or the potential success of the goals of the EAP to reduce energy use by residential and non-residential utility customers by 2035.

### Conclusion

The EAP is not a Qualified GHG Emissions Reduction Plan under CEQA pursuant to the requirements outlined in the CEQA Guidelines, Section 15183.5(b); therefore, no subsequent CEQA document can tier from the County EAP and the Project DEIR did not attempt to do so. Nevertheless, the compliance of the Project with EAP strategies has been analyzed and the Project found to be consistent with the EAP; therefore, the Project complies with Section VI(b) of the Appendix G of the CEQA Guidelines.

## Master Response 26 - Life Cycle GHG Emissions

### Comments

Several commenters have suggested that Greenhouse Gas (GHG) emissions associated with the manufacture of materials used by the Project, or the refinement of gold concentrates produced by the Project to gold products, should have been included in the DEIR in order to adequately evaluate the Project's potential GHG impacts. These comments pertain to a "lifecycle" analysis, which is not required under CEQA.

### Discussion

As described by the California Natural Resources Agency in the *Final Statement of Reasons for Regulatory Action: Amendments to the State CEQA Guidelines Addressing Analysis and Mitigation of Greenhouse Gas Emissions Pursuant to SB97* (2009):

> Moreover, even if a standard definition of the term "lifecycle" existed, requiring such an analysis may not be consistent with CEQA. As a general matter, the term could refer to emissions beyond those that could be considered "indirect effects" of a project as that term is defined in section 15358 of the State CEQA Guidelines... Depending on the circumstances of a particular project, an example of such emissions could be those resulting from the manufacture of building materials. (CAPCOA White Paper, at pp. 50-51.) CEQA only requires analysis of impacts that are directly or indirectly attributable to the project under consideration. (State CEQA Guidelines, § 15064(d).) In some instances, materials may be manufactured for many different projects as a result of general market demand, regardless of whether one particular project proceeds. Thus, such emissions may not be "caused by" the project under consideration. Similarly, in this scenario, a lead agency may not be able to require mitigation for emissions that result from the manufacturing process. Mitigation can only be required for emissions that are actually caused by the project. (State CEQA Guidelines, § 15126.4(a)(4).)

The Project will use materials including cement, steel, and various products and materials. The manufacture of many of the materials that are used by the proposed project occurs outside of Nevada County boundaries, outside of the local agencies' jurisdictional control or substantial jurisdictional influence. The project GHG emissions estimate includes the shipping of these materials to the site from an origin of 60 miles. Project operations produce gold concentrates as a final product. The project GHG emissions estimate includes the shipping of the concentrates a distance of 145 miles. Life cycle GHG emissions include indirect emissions associated with materials manufacture or production of gold products. However, these indirect emissions involve numerous parties, each of which is responsible for GHG emissions of their particular activity. The California Resources Agency, in adopting the CEQA Guidelines Amendments on GHG emissions, found that lifecycle analysis was not warranted for project-specific CEQA analysis in most situations, for a variety of reasons, including lack of control over some sources, and the possibility of double-counting emissions (see Final Statement of Reasons for Regulatory Action, December 2009). Because the amount of materials consumed during the operation or construction of the proposed project is not known, the origin of the raw materials purchased is not known, and

manufacturing information for those raw materials is also not known, calculation of life cycle emissions would be speculative. The inclusion in the DEIR analysis of indirect GHG emissions from materials used by the project or the subsequent manufacturing of gold products produced using the concentrates from the proposed project is not warranted.

### Conclusion

Therefore, consistent with state guidance, a lifecycle analysis of GHG emissions is not warranted for the project-specific CEQA analysis in the DEIR; and the DEIR's GHG impact analysis is adequate for purposes of CEQA.

## Master Response 27 - Greenhouse Gas Thresholds

### Comments

Several commenters asserted that the operational and construction greenhouse gas (GHG) thresholds set by the County for the Project's DEIR are inappropriate often stating that the County should have chosen thresholds that are lower or are "net-zero" such that any emission of GHGs over baseline would be considered a significant and unavoidable impact. For the reasons set forth below, the County's decision to choose emission of 1,100 Metric Tons (MT) of Carbon Dioxide Equivalent (CO2*e*) per year as the construction threshold and emission of 10,000 Metric Tons of Carbon Dioxide Equivalent (CO2*e*) per year as the operational threshold is authorized under the CEQA Guidelines and is supported by substantial evidence; thus, the DEIR properly analyzed impacts by using these thresholds.

### Discussion

As stated in CEQA Guidelines Section 15064.7(b), "Each public agency is encouraged to develop and publish thresholds of significance that the agency uses in the determination of the significance of environmental effects … Lead agencies may also use thresholds on a case-by-case basis as provided in Section 15064(b)(2)." Further, as stated in CEQA Guidelines Section 15064.7(c), "When adopting or using thresholds of significance, a lead agency may consider thresholds of significance previously adopted or recommended by other public agencies or recommended by experts, provided the decision of the lead agency to adopt such thresholds is supported by substantial evidence." As defined in CEQA Guidelines Section 15384(a), Substantial Evidence means "enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached."

As stated on page 4.3-42 of the DEIR, "At this time, neither the NSAQMD nor the County has adopted numerical thresholds of significance for GHG emissions that would apply to the project." Pursuant to the authority granted to lead agencies to determine the appropriate threshold for GHG emissions impacts (and other impacts) under CEQA Guidelines Sections 15064.7(b) and 15064.7(c), the County considered the GHG emissions thresholds that other California agencies had selected for CEQA analysis and considered the context of each of those thresholds. Pages 4.3-42 through 4.3-43 of the DEIR includes discussion of the GHG emissions thresholds set by the Sacramento Metropolitan Air Quality Management District (SMAQMD), the Placer County Air Pollution Control District (PCAPCD), the Bay Area Air Quality Management District (BAAQMD), and the South Coast Air Quality Management District (SCAQMD) as a basis for the County's selection of the GHG emissions thresholds to be applied to the Project.

As discussed on page 4.3-43 of the DEIR, while the nearby PCAPCD uses a construction emissions threshold of 10,000 MT CO2*e*, the County conservatively chose to apply the lower construction emissions threshold of 1,100 MT CO2*e* per year used by SMAQMD for construction

phases of land use development projects. As a basis for choosing 10,000 MT CO2*e* as the threshold of significance for operational GHG emissions, the DEIR provided the following reasoning: "For operations, because the project is an industrial project that includes stationary sources (i.e., diesel generators used for emergency power), the project's GHG emissions were compared to the 10,000 MT CO2*e* per year quantitative threshold, which, as described above, is used by SMAQMD, PCAPCD, BAAQMD, and SCAQMD for industrial and/or stationary source emissions of GHGs. The substantial evidence for this GHG emissions threshold is based on the expert opinion of various California air districts, which have applied the 10,000 MT CO2*e* per year threshold in numerous CEQA documents where those air districts are the lead agency." (DEIR, p. 4.3-43.)

Various commenters presented arguments as to why a lower threshold would be preferable; however, consistent with CEQA Guidelines Section 15384(a), the County's reasoned consideration of other agencies' GHG thresholds and selection of the most appropriate thresholds based on a comparison of the Project to the various categories used by other agencies constitutes substantial evidence as it provides "enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached." (14 CCR § 15384(a).)

Various commenters also asserted that the Project's DEIR should have evaluated emissions against a net zero GHG threshold based on the 2017 Scoping Plan and statewide GHG reduction goals. However, these commenters' opinions that any project that results in GHGs above net zero should be considered significant is inconsistent with the statewide guidance, as described in the DEIR on page 4.3-29:

> The 2017 Scoping Plan further provides that "the inability of a project to mitigate its GHG emissions to net zero does not imply the project results in a substantial contribution to the cumulatively significant environmental impact of climate change under CEQA."

As discussed above, the CEQA Guidelines allow a CEQA lead agency to determine its own thresholds for environmental impacts (including GHG emissions), and explicitly provides that an agency may consider thresholds adopted by other agencies provided that such decision is supported by substantial evidence. The County's reasoned consideration of thresholds set by other expert agencies and adoption of thresholds that are similar to those used by other agencies constitutes substantial evidence for the GHG emissions thresholds used by the County and the associated GHG emissions impact analyses.

### Conclusion

Therefore, the use of these GHG thresholds to determine the significance of the Project's GHG impacts is appropriate and legally correct pursuant to CEQA.

## Master Response 28 - Greenhouse Gas Credits

### Comments

Several commenters asserted that Mitigation Measure 4.3-7(b) is inadequate based on the holding in *Golden Door Properties, LLC v. County of San Diego* (2018) 27 Cal.App.5th 892, and that the Mitigation Measure is unenforceable, impermissibly delegates verification and enforcement authority to third parties, lacks specific performance standards, is deferred mitigation, fails to mitigate for the environmental impacts of offset projects, fails to include onsite mitigation, should involve annual purchases of credits rather than a one-time purchase, does not

require that the offsets comply with CARB protocols, and should not allow purchase of offsets based on forecasted reductions.

## Discussion

While several commenters compared the mitigation measure that was set aside in the *Golden Door* case to Mitigation Measure 4.3-7(b) in the Project's DEIR, these measures are factually distinguishable. The mitigation measure in *Golden Door* did not require that the carbon credits purchased by the applicant in that case be based on registries that are CARB approved and did not even mention the concept of protocols. This was one of the major factors that lead to the Court's decision that the mitigation measure requiring purchase of carbon credits was inadequate in that case. Conversely, Mitigation Measure 4.3-7(b) in the Project's DEIR includes explicit language requiring that the carbon credits are issued under CARB approved registries (i.e., Climate Action Reserve, the American Carbon Registry, or Verra). Likewise, while the court in *Golden Door* found that a carbon offset mitigation measure's failure to incorporate "additionality" requirement was a fatal flaw, Mitigation Measure 4.3-7(b) in the Project's DEIR clearly states that the carbon offset meet additionality requirements.

Several commenters asserted that Mitigation Measure 4.3-7(b) is unenforceable because the carbon credits could be generated in states or countries outside of CARB's jurisdiction. Mitigation Measure 4.3-7(b) requires that any carbon credits used for mitigation be obtained from a CARB-approved registry and further, comply with CARB-approved protocols to provide certainty that mitigation will be provided consistent with CARB standards. Even though no new impact has been identified, to provide an additional level of enforcement certainty, the County has modified Mitigation Measure 4.3-7(b), as shown below, to require that all carbon credits need to be generated within the State of California.

Commenters also opined that Mitigation Measure 4.3-7(b) impermissibly delegates verification and enforcement authority to third parties, purportedly because the measure requires that protocols for credits adhere to the principles set forth in the program manuals of each of the listed carbon credit registries. Mitigation Measure 4.3-7(b) clearly requires that the carbon credits comply with CARB-approved registries that implement specific protocols, so the additional requirement that the protocols comply with registry manuals does not in any manner impermissibly delegate the authority to develop protocols.

Commenters opined that Mitigation Measure 4.3-7(b) is inadequate because it lacks specific performance standards; however, Mitigation Measure 4.3-7(b) is legally adequate because it includes specific requirements for the type, quantity, source of carbon credits and specifies that the credit achieve additional, real, permanent, quantifiable, verifiable, and enforceable reductions. Nonetheless, to aid the County in enforcement of the mitigation measure, the DEIR now includes a flowchart (attached to the FEIR as Appendix F) to provide more detail on the specific performance standards required to ensure effective mitigation. Commenters also asserted that Mitigation Measure 4.3-7(b) constitutes impermissible deferred mitigation, because allegedly Mitigation Measure 4.3-7(b) lacks adequate performance standards. As discussed above, Mitigation Measure 4.3-7(b) includes specific performance standards, which have been augmented with even more specificity in the FEIR.

Commenters also asserted that Mitigation Measure 4.3-7(b) is improper because it fails to mitigate for the environmental impacts of offset projects. GHG offsets projects avoid, destruct, or sequester $CO_2e$ emissions. GHG offsets projects may be subject to environmental review such

as CEQA or NEPA; however, most GHG offset projects do not require environmental analysis as they do not result in adverse environmental impacts. For example, landfill gas destruction and beneficial use carbon offsets collect and combust landfill gas at an existing landfill and do not generate adverse environmental impacts. The various commenters raising this issue did not provide any evidence that GHG offset projects result in foreseeable environmental impacts. Therefore, analysis of impacts from GHG offset projects is not necessary.

Commenters asserted that Mitigation Measure 4.3-7(b) fails to include onsite mitigation for the Project's construction GHG emissions. However, Mitigation Measure 4.3-7(b) mitigates the Project's construction GHG emissions impacts to a less than significant level, so there is no need of further mitigation for this impact, whether onsite or offsite. There is no specific requirement that GHG emission impacts be mitigated onsite. In addition, as discussed on page 4.3-91 of the DEIR, "because climate change is a global phenomenon, a single project could not generate enough GHG emissions to contribute noticeably to climate change. However, the combination of GHG emissions from a project with other past, present, and future projects (including global anthropomorphic activities) could contribute substantially to the world-wide phenomenon of global climate change and the associated environmental impacts." Therefore, the proposed project's GHG emissions would be a local contribution to a global impact, and the location of offset mitigation is not a prerequisite for effectiveness. Even so, Mitigation Measure 4.3-7(b) was changed (as shown below) to limit to offset projects to be located within California.

Commenters also asserted that Mitigation Measure 4.3-7(b) should involve annual purchases of credits rather than a one-time purchase. However, the required one-time purchase of carbon credits mitigates the construction emissions of the Project to a less than significant level, even if such emissions occurred over several years. Moreover, the amount of mitigation required to be purchased if the Project construction schedule were spread out over several years, would likely be less than under the assumed one-year project construction schedule. For example, the current assumed one-year construction schedule results in a GHG offset responsibility of 2,345 MT $CO_2e$ (3,445 MT $CO_2e$ – 1,100 MT $CO_2e$) while under a two-year construction schedule where hypothetically, 60% of activity occurs in year 1 and 40% activity occurs in year 2, the offset responsibility would be reduced to 1,245 MT $CO_2e$ ([year 1 2,067 MT $CO_2e$ – 1,100 MT $CO_2e$] + [year 2 1,378 MT $CO_2e$ – 1,100 MT $CO_2e$]).

Commenters also asserted that Mitigation Measure 4.3-7(b) does not require that the offsets comply with CARB protocols and should not allow purchase of offsets based on forecasted reductions. As discussed previously, Mitigation Measure 4.3-7(b) clearly requires that that the offsets comply with CARB protocols. Purchase of carbon credits based on forecasted reductions is a standard approach to implementation of GHG mitigation in California; however, based on input from commenters, Mitigation Measure 4.3-7(b) has been revised to require only carbon credits based on past reductions in GHG emissions.

Even though the DEIR thoroughly addressed all impacts and mitigation, based on comments received on the DEIR, Mitigation Measure 4.3-7(b) (see page 4.3-96 through 4.3-99 of the DEIR) has been revised as set forth below (additions in double underline, deletions in ~~strikethrough~~):

***4.3-7(b)*** ***Carbon Offsets – Construction Emissions.***
*Rise Grass Valley Inc. (Rise) shall retire carbon offsets in a quantity sufficient to offset the project's construction greenhouse gas (GHG) emissions to below the 1,100 metric ton carbon dioxide equivalent (MT CO2e) per year construction threshold, consistent with the performance standards and requirements set forth below. Specifically, prior to Nevada County's (County) issuance of the project's first grading permit, Rise shall retire carbon offsets*

*equaling 2,345 MT CO2e, which was calculated by subtracting 1,100 MT CO2e (threshold) from the construction emissions generated by the project.*

***Carbon Offset Standards – Eligible Registries, Acceptable Protocols and Defined Terms:***
*"Carbon offset" shall mean an instrument, credit or other certification verifying the reduction of GHG emissions issued by the Climate Action Reserve, the American Carbon Registry, or Verra (previously, the Verified Carbon Standard). This shall include, but is not limited to, an instrument, credit or other certification issued by these registries for GHG reduction activities within the Nevada County region. The Project shall neither purchase offsets from the Clean Development Mechanism (CDM) registry nor purchase offsets generated under CDM protocols. Qualifying carbon offsets presented for compliance with this mitigation measure may be used provided that the evidence required by the "Reporting and Enforcement Standards" below is submitted to the County demonstrating that each registry shall continue its existing practice of requiring the following for the development and approval of protocols or methodologies:*

*i) Adherence to established GHG accounting principles set forth in the International Organization for Standardization (ISO) 14064, Part 2 or the World Resources Institute/World Business Council for Sustainable Development (WRI/WBCSD) Greenhouse Gas Protocol for Project Accounting; and*
*ii) Oversight of the implementation of protocols and methodologies that define the eligibility of carbon offset projects and set forth standards for the estimation, monitoring and verification of GHG reductions achieved from such projects. The protocols and methodologies shall:*

*a. Be developed by the registries through a transparent public and expert stakeholder review process that affords an opportunity for comment and is informed by science;*
*b. Incorporate standardized offset crediting parameters that define whether and how much emissions reduction credit a carbon offset project should receive, having identified conservative project baselines and the length of the crediting period and considered potential leakage and quantification uncertainties;*
*c. Establish data collection and monitoring procedures, mechanisms to ensure permanency in reductions, and additionality and geographic boundary provisions; and,*
*d. Adhere to the principles set forth in the program manuals of each of the aforementioned registries, as such manuals are updated from time to time.*
*e. Be approved by the California Air Resources Board, and be compliant with 17 CCR § 95972 and AB 32 (the California Global Warming Solutions Act of 2006) to the extent applicable to voluntary offsets.*

*Further, any carbon offset used to reduce the project's GHG emissions shall be a carbon offset that represents the past ~~or forecasted~~ reduction or sequestration of one MT of CO2e that is "not otherwise required" (CEQA Guidelines Section 15126.4[c][3]). Each carbon offset used to reduce GHG emissions shall achieve additional, real, permanent, quantifiable, verifiable, and enforceable reductions, which are defined for purposes of this mitigation measure as follows:*

i) *"Additional" means that the carbon offset is ~~not~~ in addition to: (1) any greenhouse gas emission reduction otherwise required by law or regulation; ~~and not~~ (2) any other GHG emissions reduction that otherwise would occur; and (3) is consistent with Health and Safety Code Section 38562(d)(2);*
ii) *"Real" means that the GHG reduction underlying the carbon offset results from a demonstrable action or set of actions, and is quantified under the protocol or methodology using appropriate, accurate, and conservative methodologies that account for all GHG emissions sources and sinks within the boundary of the applicable carbon offset project, uncertainty, and the potential for activity shifting leakage and market-shifting leakage;*
iii) *"Verifiable" means that the GHG reduction underlying the carbon offset is well documented, transparent and set forth in a document prepared by an independent verification body that is accredited through the American National Standards Institute (ANSI);*
iv) *"Permanent" means that the GHG reduction underlying the carbon offset is not reversible; or, when GHG reduction may be reversible, that a mechanism is in place to replace any reversed GHG emission reduction;*
v) *"Quantifiable" means the ability to accurately measure and calculate the GHG reduction relative to a project baseline in a reliable and replicable manner for all GHG emission sources and sinks included within the boundary of the carbon offset project, while accounting for uncertainty and leakage; and*
vi) *"Enforceable" means that the implementation of the GHG reduction activity must represent the legally binding commitment of the offset project developer to undertake and carry it out.*

*The protocols and methodologies of the Climate Action Reserve, the American Carbon Registry, and Verra establish and require carbon offset projects to comply with standards designed to achieve additional, real, permanent, quantifiable, verifiable and enforceable reductions. Additionally, the "Reporting and Enforcement Standards" below ensure that the emissions reductions required by this mitigation measure are enforceable against Rise, as the County has authority to hold Rise accountable and to take appropriate corrective action if the County determines that any carbon offsets do not comply with the requirements set forth in this mitigation measure.*

*The above definitions are provided as criteria and performance standards associated with the use of carbon offsets. Such criteria and performance standards are intended only to further construe the standards under CEQA for mitigation related to GHG emissions (see, e.g., State CEQA Guidelines Section 15126.4(a), (c)), and are not intended to apply or incorporate the requirements of any other statutory or regulatory scheme not applicable to the project (e.g., the Cap-and-Trade Program).*

*Additionally, the County shall require that all carbon offsets purchased by the Project applicant shall originate from inside the state of California.*

***Reporting and Enforcement Standards:***
*Prior to issuance of requested grading permits, Rise shall submit a report to the County that identifies the quantity of emission reductions required by this mitigation measure, as well as the carbon offsets to be retired to achieve compliance with this measure. For purposes of demonstrating that each offset*

*is additional, real, permanent, quantifiable, verifiable and enforceable, the report shall include: (i) the applicable protocol(s) and methodologies associated with the carbon offsets, (ii) the third-party verification report(s) and statement(s) affiliated with the carbon offset projects, (iii) the unique serial numbers assigned by the registry(ies) to the carbon offsets to be retired, which serves as evidence that the registry has determined the carbon offset project to have been implemented in accordance with the applicable protocol or methodology and ensures that the offsets cannot be further used in any manner, and information sufficient for the County to verify that the purchased offsets meet the requirements identified within this mitigation.*

*To ensure consistent and effective enforcement of this mitigation measure and to assist the County with its review of the report described above, an implementation process timeline and associated flow chart for the implementation and administration of this mitigation measure's requirements has been prepared and is attached as Appendix F to the FEIR.*

*If the County determines that the project's carbon offsets do meet the requirements of this mitigation measure, the offsets can be used to reduce project GHG emissions and project permits shall be issued. If the County determines that the project's carbon offsets do not meet the requirements of this mitigation measure, the offsets cannot be used to reduce project GHG emissions and project permits shall not be issued. Additionally, the County may issue a notice of non-consistency and cease permitting activities in the event that the County determines the carbon offsets provided to reduce project GHG emissions are not compliant with the aforementioned standards. In the event of such an occurrence, project permitting activities shall not resume until Rise has demonstrated that the previously provided carbon offsets are compliant with the standards herein or have provided substitute carbon offsets achieving the standards of this mitigation measure in the quantity needed to achieve the required emission reduction. In the event that the project is out of compliance with this Mitigation Measure and fails to demonstrate compliance after receiving notice of said violation, the County shall have authority to impose administrative penalties, take legal action to force compliance, or to start proceedings to suspend or revoke the Project's permits.*

### Conclusion

As discussed above, Mitigation Measure 4.3-7(b) is distinguishable from the mitigation measure in the *Golden Door* case and complies with all legal requirements for mitigation measures involving purchase of carbon credits. Moreover, although no new impacts have been identified, the County has revised Mitigation Measure 4.3-7(b) to further address concerns raised by commenters and to clarify with certainty that the carbon credits will effectively mitigate the Project's impacts from construction-related emissions of greenhouse gas to a less than significant level. Thus, the DEIR adequately mitigates the Project's construction GHG emissions.

## Master Response 29 - Near Surface Workings and Subsidence

### Comments

Several commenters asserted that the Project would cause hazards due to the collapse of near surface workings, or deep mine workings when the mine is dewatered, which could result in impacts to surrounding properties (e.g., above-ground structures and residents) atop the underworkings.

## Discussion

As discussed on pages 4.6-44 to 4.6-49 of the DEIR, under Impact Statement 4.6-3 related to unstable geological units, the potential collapse of near surface mine workings was evaluated and Mitigation Measure 4.6-3(c) was included in the DEIR to close six near surface mine features, resulting in a less-than significant impact relating to potential collapse of mine features.

As discussed on page 4.6-12 of the DEIR, the current water elevation in the mine is approximately 2,500 feet above mean sea level. In order to recommence mining, the underground mine must be dewatered, and groundwater entering the mine must be continuously pumped during the mining operation. When the water level in the mine workings is located near the ground surface, the drawdown of groundwater within the mine workings may increase the potential for settlement or collapse of shallow workings that were not formally closed. (see DEIR, pp. 4.6-44 to 4.6-49.) Near surface workings that are already in a dewatered state would generally not be significantly impacted by dewatering the mine. As shown on Drawing A207, including in Appendix H.6 to the DEIR, the current water level in the mine is only close to the surface in the area near the Idaho shaft near Idaho Maryland Road. All near surface mine workings were specifically evaluated by NV5 in the Geotech Review of Near Surface Features, as shown in Table 1 of Appendix H.6.

As discussed on page 4.6-44 of the DEIR, potential for collapse of existing near-surface mine features as a result of the proposed project was evaluated by NV5, whose report was independently peer reviewed by the County's consultant, ECM. Mitigation Measure 4.6-3(c) required the closure of six mine features.

As stated on page 2 of Appendix H.6, near-surface mine features are generally more susceptible to subsidence and collapse than are deeper mine workings, because the near-surface features may be located in weaker materials (soil and weathered rock); whereas the deeper mine workings are commonly located in competent bedrock. In addition, the underground mine workings focused on removal of quartz vein materials that are generally narrow, so the collapse of a deep (e.g., 100 feet bgs) mine feature is not likely to be expressed at the ground surface. The County's independent expert ECM is in agreement with NV5 and based on the known physical characteristics of the rock units, considered a 100-foot distance below ground surface to be conservative (page 33 of Appendix H7), meaning that NV5 believed that collapse of features even closer to the surface than 100 feet bgs are unlikely to be expressed on the surface. Furthermore, flooded workings that are not already closed or proposed to be closed are greater than 165 feet below surface (see Drawing 207 in DEIR Appendix H.6) and therefore underground workings that have potential to cause subsidence at surface have been thoroughly analyzed in the DEIR.

Once the mine is dewatered, new mining excavations will be constructed as described on page 3-19 of the DEIR. To provide access to the gold mineralization, a network of tunnels and raises would be constructed throughout the life of the mine. The tunnels would be constructed in the nonmineralized rock which, at the mine, is typically meta-andesite volcanic rock. Modern ground support, which may include rock bolting and screens, would be installed in tunnels as deemed necessary to ensure a safe work environment and in accordance with best mining practices coupled with routine inspections by the US Mine Health and Safety Administration (MSHA). Therefore, it is unlikely that any new underground openings would produce a fall of ground or collapse that would affect the integrity of the mine. Except for the new Service Shaft, all of these new workings would be at least 500 feet below ground surface and therefore too deep to cause subsidence at surface even if they were to collapse. As described on page 3-19 and 3-20 of the DEIR, production blasting is used to create underground openings, and these openings are then refilled with cemented paste backfill. Backfilling re-supports the rock within and around the original opening preventing caving and resulting in stability in the deep part of the mine. This stability at

depth carries upwards, thus eliminating the possibility of the mining producing any voids that would reach the surface or near surface.

### Conclusion

The DEIR's evaluation of the potential for dewatering to result in collapse of surface materials is legally adequate and based on expert analysis, independently reviewed and corroborated by the County's independent consultant.

## Master Response 30 - Biological Study Technical Adequacy

### Comments

Several commenters questioned the adequacy of the biological technical reports, specifically the timing and methodology of surveys.

### Discussion

As summarized in section 4.4.1, "Introduction," and 4.4.4, "Method of Analysis," of the DEIR, and included as Appendix F, eleven different technical reports were prepared that characterize and analyze the biological resources, habitat, and waters within the Project site. These technical reports were prepared by biologists with over 30 years of combined local expertise in the species and environment within the Project site, and in accordance with federal, state, and local regulations and agency-authored manuals. For example, the aquatic resource delineations prepared for the Centennial Site and Brunswick Area followed U.S. Army Corps of Engineers manuals for conducting wetland delineations.[15] As another example, the botanical field surveys were conducted in accordance with the relevant California Department of Fish and Wildlife guidance.[16] These technical studies were then peer reviewed by the County and their biological consultant. The peer review was conducted by a biological resources firm (Madrone) with similar local experience that resulted in several rounds of review and revision prior to the County's acceptance of these reports for use in the DEIR. As a result, numerous biological experts with local knowledge have analyzed, and reviewed the characterization and analysis included in these biological technical reports prior to their use and incorporation into the DEIR. Specifics regarding methodology and timing of surveys for rare plants is found in Master Response 31 (Rare Plants) and amphibians is addressed in Master Response 38 (Foothill Yellow Legged Frog and California Red Legged Frog).

In addition to the biological resources assessment reports and aquatic resource delineations, management plans were also prepared in accordance with Nevada County Land Use and Development Code (Section L-II 4.3.3) to minimize Project impacts to certain biological resources (i.e., aquatic resources, Pine Hill flannelbush) to the maximum extent possible. These management plans were similarly peer reviewed by the County's biological consultant.

The biological studies and management plans were the basis of scientific evidence used by the County to determine whether the Project would trigger any of the thresholds of significance identified in Chapter 4.4, Biological Resources, of the DEIR, and thus, result in significant effects to biological resources. The thresholds of significance used in the DEIR are based on Appendix G of the CEQA Guidelines (Section IV).

[15] *Corps of Engineers Wetlands Delineation Manual* (Environmental Laboratories, 1987) and *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys and Coast Regions* (Version 2.0) (Corps, 2010).
[16] *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Sensitive Natural Communities (CDFW 2018).*

In general, the biological resources surveys conducted for this Project were reconnaissance-level in nature, and were conducted primarily to identify *habitat* for special-status species. Protocol-level surveys were conducted for plants, which are not mobile. The wildlife species with potential to occur in the area are highly mobile; as a result, negative protocol-level surveys would not be informative in regard to their presence or absence from a site during construction a year or more in the future. As a result, it is common practice to adopt a more conservative approach whereby one maps habitats on-site and assumes a species could be present if suitable habitat is present. Focused surveys for a species are conducted shortly prior to construction to ensure that any individuals of a species that are present at that time are appropriately protected and avoided.

### Conclusion

Therefore, the DEIR thoroughly identified, analyzed and mitigated, as necessary,_ Project impacts to biological resources.

## Master Response 31 - Rare Plants

### Comments

Several commenters assert that the rare plant surveys were not conducted during the appropriate times of the year, and thus, certain special-status plants occurring on the Sites may not have been detected.

### Discussion

As summarized in DEIR section 4.4.1 and Appendix F, protocol-level rare plant surveys were conducted within the Project site in December 2019 and July and August 2020. The survey dates in July and August 2020 were at a time of year when most of the potential rare plants would be blooming. In addition, following release of the DEIR, an additional rare plant survey of the Project site was conducted in June 2022 to address comments regarding the potential that July and August 2020 surveys were conducted outside published blooming periods and may have missed potential rare plants that may bloom earlier in the year. Please see Appendix G to this Final EIR for the Technical Memo for Botanical Resource Surveys at the Brunswick Mine and Centennial Study Areas (June 2022). The June 2022 rare plant survey did not identify any new rare or special-status plant species but did identify that many of the Pine Hill flannelbush had burned in the recent fire and germination of seedlings around these plants existed. In addition, during Visual Encounter Surveys for foothill yellow-legged frog in June 2022, two populations of giant checkerbloom (*Sidalcea Gigantea*) were identified in upland riparian areas adjacent to South Fork Wolf Creek. Giant checkerbloom has no federal status and is CNPS list 4.3 (not very threatened in California and limited distribution or infrequent throughout a broader area in California).

As summarized in DEIR section 4.4.2, 23 CNPS ranked plants and special-status plant species were identified as occurring within a nine Quad search of the Project site. The majority of the identified plant species were dismissed from further consideration in the DEIR due to a lack of suitable habitat on the Project site, being substantially outside of the known range and distribution for the plant species, or both. Ten plant species were analyzed in the DEIR (see DEIR section 4.4.2 and Impact 4.4-1.). Of these ten species, only four have a moderate to high potential of occurring within the Project site, including the Scadden Flat checkerbloom (List 1B.1), brownish beaked-rush (List 2B.2), Sierra blue grass (List 1B.3), and Pine Hill flannelbush (federally endangered and List 1B.2).

Surveys for those List 1 and List 2 species with a potential to occur within the Project site were conducted within the appropriate blooming periods. Surveys were conducted on June 20, 21, and 28. The blooming periods for potential special-status species plants that may occur onsite are

May through August with the additional surveys conducted on June 20, 21, and 28, covering each of the List 1 and List 2 species except for brownish beaked-rush and Scadden Flat checkerbloom with blooming periods between July and August. However, brownish beaked-rush and Scadden Flat checkerbloom have a low potential to occur within the Project site and neither species was identified during the July and August 2020 surveys of the project site.

In addition, a reference site visit was conducted for the finger rush at the location identified within the mapped CNDDB location for the species on June 24, 2019, and it was determined that the species was identifiable and therefore, it would have been identifiable during the special-status plant surveys conducted in early July 2019. The species was not identified and is considered to have a low potential to occur within any of the proposed areas of disturbance. Chaparral sedge, a perennial herb, and Red Hills soaproot, a perennial bulbiferous herb, have a low potential to occur within the areas of proposed disturbance and they were not identified during special-status plant surveys conducted in early July 2019. Both species are perennial and neither species was identified within the areas of proposed disturbance based on a comprehensive survey and keying out the characteristics of each plant species identified during the special-status plant species surveys. Neither the finger rush (April to June blooming period), chaparral sedge (March to June blooming period), or Red Hills soaproot (May to June blooming period) were documented within the Project site during the botanical surveys conducted on June 20, 21, and 28, 2022.

Disturbance related impacts to CNPS list 3 and list 4 species would not be considered a "significant" impact requiring additional mitigation under CEQA Guidelines Section 15380. As a result, impacts to List 3 and List 4 species identified as potentially occurring within the Project site, including the Humboldt lily and Sierra brodiaea (both List 4 Species,) do not meet the CEQA Guidelines Section 15380 definitions as either "endangered," "threatened," or "rare". Therefore, per the analysis of special-status plant species covering the entirety of the Project disturbance areas, special-status plant surveys were conducted within the known blooming season for each of the potential special-status plant species identified as part of the initial background research and analysis except for three (3) species that are CNPS list 1 and 2 species. Those species include the finger rush, chaparral sedge, and Red Hills soaproot and the June 2022 surveys confirmed that none of these three species are located within the Project site.

Based on this extensive technical analysis and detailed peer review, the DEIR concluded Project-related surface disturbance could have a potential to impact special-status plant species or habitat that may contain special-status plant species. As a result, the DEIR included Mitigation Measure 4.4-1 requiring a management plan for the impacts to the Pine Hill flannelbush and pre-construction special-status plant species surveys. The preconstruction special-status plant survey would include an additional survey for these and other special-status plant species with potential to occur within the Project's areas of disturbance.

## Conclusion

Therefore, special-status plant surveys were conducted within the known blooming season for each of the potential special-status plant species occurring within the project area. Nevertheless, potentially occurring special-status plant species that may not have been in bloom during previously conducted surveys would 1) be identified prior to the implementation of the proposed disturbance and 2) would be fully mitigated per the mitigation measures outlined within the DEIR to avoid, minimize, and mitigate for potential impacts to special-status plant species.

# Master Response 32 - Temperature of Mine Water Discharge

## Comments

The County received several comments that asserted the Project would cause significant impacts due to increases in natural water temperature in the South Fork of Wolf Creek, which could lead to downstream effects on aquatic organisms and violation of NPDES permitting requirements for treated water discharge.

## Discussion

Prior to discharging any mine water to the South Fork of Wolf Creek, the mine operator must first obtain coverage under the Central Valley Regional Water Quality Control Board (RWQCB) General Order for Limited Threat Discharges to Surface Waters (R5-2022-006), which General Order requires that natural water temperatures in the creek not be raised by more than 5°F, in addition to monitoring requirements that will be included in the Notice of Applicability issued by the RWQCB. Further, during periods of low flow in the creek, when discharge temperature could potentially result in an exceedance of the 5°F limit, discharge volume reductions will be used to ensure compliance with the General Order and to ensure no significant impacts related to increased water temperature will occur.

As discussed on page 4.8-31 of the DEIR, the RWQCB adopted a Water Quality Control Plan, Fifth Edition, for the Sacramento and San Joaquin River Basins (hereinafter Basin Plan) that designates beneficial uses, establishes water quality objectives, and contains implementation programs and policies to achieve those objectives for all waters addressed through the plan. The Basin Plan, at page 2.3, states that the "…beneficial uses of any specifically identified water body generally apply to its tributary streams." The Basin Plan does not specifically identify beneficial uses for South Fork of Wolf Creek but does identify present and potential uses for the Bear River, to which the South Fork of Wolf Creek and Wolf Creek, is tributary. As stated in note 2 of Table 2-1 of the Basin Plan, any segments with both COLD and WARM beneficial use designations will be considered COLD water bodies for the application of water quality objectives. Therefore, the COLD beneficial use is applicable to South Fork Wolf Creek.

Mitigation Measure 4.8-1(a) requires the applicant to submit a Notice of Intent (NOI) to the RWQCB and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. NPDES CAG995002 General Order R5-2022-006 requires that natural temperatures not be increased by more than 5°F (2.8°C). Regular receiving water monitoring is required with a frequency specified in the NOA sufficient to evaluate the impacts of the discharge and compliance with the General Order. Regular receiving water monitoring data, measured at the upstream and downstream monitoring locations identified in the NOA, are used to determine compliance. (p. 50 of R5-2022-006).

As stated on page 108 of Appendix K.2, after being pumped from the mine, the water would be stored within a surface pond before treatment and discharge. The temperature of the water within the mine workings and drains remains relatively constant, between 14 and 15 degrees Celsius (~58°F). During the summer the temperature of the mine water would be comparable to the temperature of the receiving water in South Fork Wolf Creek. Measured temperatures in South Fork Wolf Creek are greater than 11.7°C (53°F) from May though September (see Table 4 below) and therefore water temperature of the mine discharge is not of concern during these months. During the winter, the ambient temperature should cool the water in the pond (see below for more discussion). In addition, the dilution with upstream flows would lower temperatures depending on the rate of flow and temperature versus the discharge from the water treatment plant. As is

presented in the record of streamflow in appendix I of Appendix K.2, there are times when natural temperature of South Fork Wolf Creek is low, which coincide with low flow rates. If necessary, the reduction in mine water discharge would provide an operational tool to ensure compliance with the temperature requirements of the water discharge permit. As such, if the discharge water temperature and volume would result in a temperature increase above 5°F during low flow rate periods, the Project would reduce discharge volume to stay within the temperature range allowed by the General Order during those low flow periods. While flows would not likely need to be reduced below 850 gpm to meet discharge temperature requirements (see discussion below), flows could be reduced below the maximum discharge of 2,500 gpm by simply reducing the pumping rate from the mine into the pond for the period in which the reduction is required. In an unlikely scenario where discharge flow needs to be reduced below 850 gpm to achieve discharge temperature requirements, additional water could be stored in the pond, and if necessary, the maintenance pumping rate could be reduced to allow water storage in the lowest levels of the mine until the flow reduction is no longer necessary to meet temperature requirements.

The natural temperature of South Fork Wolf Creek is correlated to the ambient air temperature with seasonal highs and lows regulated by ground contact (see Figure 25 below). A lower ambient temperature will also influence the temperature of water in the water treatment pond.

The calculation of the heat loss from the pond will vary depending on the weather conditions throughout the operation. However, the operation can influence the water discharge temperature in order to meet the requirements based on natural creek temperature. The flowrate of the mine water discharge can be reduced when natural temperature of South Fork Wolf Creek is low and coincides with low flow rates, if necessary to ensure compliance with the General Order. The maximum discharge rate of 2,500 gpm is equal to 1,249,500 pounds of water per hour and the operational discharge rate of 850 gpm is equal to 424,800 pounds of water per hour. One BTU is the amount of heat energy required to raise one pound of water by 1°F. Assuming an extreme case where mine water temperature must be reduced by 10°F, the required heat loss at 850 gpm would be 4.2 million BTU/hr versus 12.5 million BTU/hr at 2,500 gpm. The reduction of flow would therefore dramatically influence the water temperature of the discharge given a constant heat loss from the pond.

The majority of heat loss from the pond surface is a result of evaporation and the surface heat loss can be expressed as the heat loss factor multiplied by the temperature difference and surface area of the pond. Assuming mine water temperature of 58.1°F[17] and ambient air temperature of 39.3°F[18], the surface area of the pond of 113,587 $ft^2$, and a surface heat loss factor of 5.5 BTU/hr[19], the heat loss from evaporation would be up to 11.7 million BTU/hr (~2,470 BTU/ $ft^2$/day). This number is similar to the extreme case requirement of 12.5 million BTU/hr at 2,500 gpm and approximately 3 times larger than the 4.2 million BTU/hr requirement at 850 gpm.

Heat loss from radiation is on the order of 2,400 to 3,600 BTU/ $ft^2$/day and conduction less than 500 BTU/ $ft^2$/day. Solar radiation generally adds between 300 to 2,800 BTU/ $ft^2$/day and atmospheric radiation generally adds between 2,400 to 3,200 BTU/ $ft^2$/day (Hanford 1972). Heat gain from solar radiation would be lower during the late/fall or winter and the net heat loss from these processes would be minor in comparison to the heat loss from evaporation.

[17] 14.5 degree Celsius is median of estimated range on page 108 of Appendix K.2
[18] Average air temperature in November 2020 measured at SF Wolf Creek Discharge point
[19] Surface heat loss factor of 5.5 is midrange of values for sheltered position with wind velocity of 2 to 5 mph. https://www.engineeringtoolbox.com/swimming-pool-heating-d_878.html . Average windspeed in area is approximately 6 mph. https://wind.willyweather.com/ca/nevada-county/grass-valley.html

This example demonstrates that substantial cooling would occur in the water treatment pond during periods of low temperature and low flows in South Fork Wolf Creek. The reduction of discharge flow would reduce the required heat loss proportionally and provides a feasible tool to ensure compliance with the temperature requirements for the mine water discharge.

## Conclusion

In summary, the Project will be subject to the State's General Order, which requires that discharge not increase natural temperatures of the creek by more than 5°F, and discharge flow reduction provides an adequate mechanism to ensure compliance even during low flow conditions in the creek. The EIR analysis demonstrates that the proposed discharge of treated water into South Fork Wolf Creek is regulated by the State permitting process and would not result in adverse effects to downstream water quality and aquatic organisms.

**Water and Air Temperature Measured at South Fork Wolf Creek Discharge Point (Plotted from Table 4)**

## Master Response 33 - Groundwater Dependent Vegetation

### Comments

Several commenters have expressed concerns about the impact of mine dewatering, and lowering of groundwater levels, on groundwater dependent vegetation, which could lead to drying up of vegetation and increase in fire hazard. As explained below, this concern is addressed in the Wildfire chapter of the DEIR (DEIR, p. 4.13-21).

## Discussion

Most vegetation in the Project are not groundwater dependent. Terrestrial vegetation, such as Ponderosa Pine, Incense Cedar, Douglas Fir, and California Black Oak in the project area have roots depths typically less than 6 feet[20] which are within the unsaturated zone (above the water table and capillary fringe). Mature ponderosa pines put down a root to depths of more than 2 m (6 ft) in porous soils, but seldom more than 1 m (3 ft) in heavy clay soils. Exceptions occur in soils underlain by rock with deep fissures, where roots have been observed along cut banks at depths of 11 to 12 m (35 to 40 ft). However, the main mass of roots is concentrated within the top 60 cm (24 in) of the soil mantle[21]. Plant roots occupy this unsaturated zone because it contains air, and oxygen is essential to root respiration. As discussed on page 4.13-21 of the DEIR, in the areas away from the creeks and valleys, the depth to groundwater is typically greater than 10 feet and, in many cases, may be 100 feet or more. In addition, the normal seasonal fluctuation in the depth to groundwater may be 10 feet to 30 feet or more. Thus, in the areas away from the creeks, the existing groundwater surface is below the typical depth of rooted vegetation and tap roots from trees, especially during the drier months when the depth to groundwater is at its greatest. Therefore, terrestrial vegetation, which is not groundwater dependent, will not be affected by groundwater drawdown induced by mine dewatering.

At the location of the perennial streams, South Fork Wolf Creek and Wolf Creek, the groundwater level is at or above the level of the streambed. These streams have developed valleys along their courses. Groundwater levels are shallow in the valley bottoms. Hydrophytic vegetation are plants which have adapted to growing in the low-oxygen conditions associated with prolonged saturation or flooding. These plants therefore are dependent on the saturated soil conditions provided by the capillary fringe above the water table. In order to create these saturated soil conditions, the water table must be close to surface and the soil type must have small pores, such as silt or clay, in order to create a sufficient height of capillary fringe. Meadows develop in areas where there is a shallow water table and an accumulation of fine-textured soils, often with rich organic layers that are needed to draw water to shallow rooted meadow plants by capillary rise[22]. As discussed on page 4.13-21 of the DEIR, discharge of treated water to South Fork Wolf Creek would prevent the lowering of the groundwater levels along the reach of that creek because the full dewatering volume would be discharged to the creek, whereas only a small fraction of the groundwater that would be removed from the subsurface would come from that area. Thus, the potential increased recharge due to the enhanced base flow in South Fork Wolf Creek would more than offset any effects from dewatering in the area near the creek. In order to clarify that groundwater drawdown induced from the mine would not impact groundwater dependent (phreatophytic) vegetation, Itasca Denver prepared a memo showing the simulated drawdown in selected meadows which is attached to the Final EIR as Appendix H. These three meadows (Brunswick Site, Empire Mine Park, and Loma Rica) would experience minimal drawdown, even without consideration of the mine water discharge to South Fork Wolf Creek. With the addition of 1.9 cfs (850 gpm) (average maintenance dewatering rate), future mining is predicted to have no to very little groundwater drawdown in the vicinities of the meadows. (see Itasca Memo – Simulated Drawdown of Selected

[20] It should be noted that the root depths referred to on page 121 of Appendix K.2 represent extreme cases. Mature ponderosa pines put down a root to depths of more than 2 m (6 ft) in porous soils, but seldom more than 1 m (3 ft) in heavy clay soils. Exceptions occur in soils underlain by rock with deep fissures, where roots have been observed along cut banks at depths of 11 to 12 m (35 to 40 ft). The main mass of roots is concentrated within the top 60 cm (24 in) of the soil mantle.
(see source material at (https://www.srs.fs.usda.gov/pubs/misc/ag_654/volume_1/pinus/ponderosa.htm)
[21] https://www.srs.fs.usda.gov/pubs/misc/ag_654/volume_1/pinus/ponderosa.htm
[22] https://www.fs.usda.gov/Internet/FSE_DOCUMENTS/stelprdb5434345.pdf

Meadows attached to the Final EIR as Appendix H). As such, this impact is still considered less than significant.

### Conclusion

The DEIR provides substantial evidence (Chapter 4.13) that the dewatering operations would not adversely impact surface level vegetation leading to the indirect effect of providing more dry fuel sources and increasing wildfire risk. Appendix H to this Final EIR provides supplemental evidence, corroborating the findings in the DEIR that dewatering would not increase fire risk due to reduced groundwater levels.

## Master Response 34 - Resident Fish

### Comments

Several commenters questioned the Project's potential impact on resident fish and their habitat in South Fork Wolf Creek. As discussed below, brown trout and bluegill were identified within South Fork Wolf Creek; however, these are not special-status species, and rather, are invasive species. Nonetheless, the Project will not cause significant impacts to fish due to the requirement that the Project obtain coverage under the Central Valley Regional Water Quality Control Board's limited threat discharge order, which requires that discharge meet water quality standards and limit temperature change to receiving waters.

### Discussion

The March 23, 2022 CDFW reporting on electrofishing samples collected by the agency in early March 2022 at three (3) distinct sampling locations identified two fish species, brown trout and bluegill, within South Fork Wolf Creek (see Agency Letter 3 of this Final EIR). Both the brown trout and bluegill are non-native species and though they may be resident within stretches of South Fork Wolf Creek, these species have no state or federal protections given their status as non-native fish species.

The sampling location closest to the daylighting of South Fork Wolf Creek within the Brunswick Site included three brown trout that were considered to be of "poor body condition" and "the fish were thinly distributed with plenty of unoccupied habitats between fish occurrences." Furthermore, CDFW concluded that "these preliminary data suggest that Brown Trout migrate into this site from more ideal spawning and rearing habitats downstream."

CDFW also concluded that fish captured in Site 2 were of good body condition with healthy fins and no visible signs of disease. Site 2 had the highest fish density and diversity of Brown Trout sizes suggesting that Site 2 is a spawning and rearing location for Brown Trout. Fish captured in Site 3 were of good body condition with healthy fins and no visible signs of disease. The results of CDFW electroshocking suggest that the best habitat within South Fork Wolf Creek between the Brunswick Site and Highway 174, where the creek is culverted underground along Highway 174 before daylighting closer to the City of Grass Valley, lies within the stretch within the Bennett Street Grasslands when compared to the location closer to the Brunswick Site upstream where there were fewer non-native fish that were in "poor body condition."

For potential indirect downstream impacts to fish species and aquatic and riparian habitat along South Fork Wolf Creek, including the area located within the Bennett Street Grasslands, from the proposed 5.6 cfs discharge limit within South Fork Wolf Creek, the applicant must remain in compliance with the National Pollutant Discharge Elimination System (NPDES) discharge requirements covering the discharge to South Fork Wolf Creek. The NPDES discharge requirements are mandated by the State Water Resources Control Board. The Clean Water Act

(CWA) requires all point source discharges from mining operations, including discharges from associated impoundments, be authorized under an NPDES permit. The NPDES program regulates discharges from three general categories of mining activities as well as the considerations associated with abandoned mines. For the proposed project, the hard rock mining NPDES permit discharge limits must be adhered to.

Therefore, remaining in compliance with the NPDES discharge requirements covering the discharge to South Fork Wolf Creek will ensure that the proposed discharge will not have an adverse effect on the South Fork Wolf Creek aquatic ecosystem and any sensitive aquatic biological resources, including fish and aquatic habitat along South Fork Wolf Creek. Remaining within the NPDES discharge limit of 5.6 cfs, potential bank erosion, bed scour, and channel avulsion would not be substantial and water quality standards for constituents and parameters of concern would remain in compliance. These parameters of concern include temperature, siltation, and turbidity within South Fork Wolf Creek and downstream to the Bennett Street Grasslands.

Therefore, negative impacts to aquatic resources, including fisheries, downstream of the Brunswick Site from excess siltation and turbidity, as well as from exceeding safe threshold limits caused by the proposed discharge, would be avoided and minimized by staying within the required NPDES discharge limits as part of the proposed discharge to the South Fork Wolf Creek. This would include minimizing any potential changes in water temperature per the NPDES discharge limits and requirements.

### Conclusion

Any potential impacts to fish and aquatic habitat within South Fork Wolf Creek would be less than significant given the stringent requirements of the NPDES discharge requirements and the high levels of water treatment that will be implemented prior to discharging to South Fork Wolf Creek.

## Master Response 35 - Discharge to South Fork Wolf Creek

### Comments

Several comments received on the DEIR focus on the discharge of water to South Fork Wolf Creek from the New Brunswick Industrial Site. Various comments assert the discharged water would contain pollutants, contaminate the creek, or damage the surrounding ecosystem. As demonstrated in the DEIR, any outflow of groundwater to South Fork Wolf Creek resulting from the dewatering of the Idaho-Maryland Mine will be treated in accordance with strict regulatory standards prior to discharge. In fact, the water quality of the groundwater to be discharged, after on-site treatment, will exceed the existing water quality levels of surface water in South Fork Wolf Creek.

### Discussion

#### Dewatering Process

As discussed in the Project Description of the DEIR (Chapter 3), to reinitiate the underground mining and gold mineralization process, the Project applicant is proposing to dewater the underground mine workings of the Idaho-Maryland Mine, which has been flooded since the mid-1950s. The initial dewatering process will be accomplished by using the New Brunswick shaft to access the underground mine workings and place submersible and staged centrifugal pumps to pump the water out of the shaft through a pipeline. (DEIR, p. 3-15.) As measured by the New Brunswick shaft, the groundwater level currently sits at approximately 260 feet below ground surface (bgs). (DEIR, p. 3-15.) The submersible pump will gradually pump water out of the shaft

at approximately 5.6 cubic feet per second (cfs), or 2,500 gallons per minute (gpm). (DEIR, p. 3-15.) Over the first six-month period, the Project applicant will pump approximately 2,500 acre-feet from the underground mine workings through the pipeline and into an existing clay-lined settling pond with an approximate 40-acre-foot total capacity. (DEIR, p. 3-15.) From the clay-lined settling pond, the water will then be moved through a water treatment system to meet or exceed applicable water quality objectives and then be discharged to South Fork Wolf Creek. (DEIR, p. 3-18.) Any discharge of water to South Fork Wolf Creek will be performed under a discharge permit from the Central Valley Regional Water Quality Control Board (CVRWQCB), with required monitoring and reporting, to ensure that discharge water meets all applicable water quality standards. (DEIR, p. 4.8-28.)

## Water Quality

Water samples of the groundwater from the underground mine indicate the primary constituents of concern are iron and manganese. (DEIR, p. 4.8-21). Within the New Brunswick shaft, the iron concentration ranges from 1,400 micrograms per liter (µg/L) to 1,600 µg/L. (DEIR, p. 4.8-21). The secondary drinking water maximum contaminant level (MCL) and the National Pollutant Discharge Elimination System (NPDES) effluent limit for iron are both 300 µg/L. (DEIR, p. 4.8-21). For manganese, the groundwater samples indicate concentration ranges from 230 µg/L to 270 µg/L. (DEIR, p. 4.8-21). The MCL and NPDES effluent limit for manganese are both 50 µg/L. Arsenic also was detected in the New Brunswick groundwater samples below the MCL and NPDES effluent limit of 10 µg/L. (DEIR, p. 4.8-21).

The New Brunswick groundwater samples also detected the compound cis-1 ,2-dichloroethylene (cis-1 ,2-DCE). This compound generally occurs as a breakdown product of industrial solvent trichloroethylene (TCE) or the dry-cleaning solvent tetrachloroethylene (PCE). (DEIR, p. 4.8-21). The presence of cis-1 ,2-DCE may be attributable to two potential sources: either a historic solvent used within the New Brunswick mine for equipment repair and maintenance, or a seepage from the adjacent former SPI Mill Site to the southeast. The SPI Mill Site was known to have industrial solvent impacts. (DEIR, p. 4.8-21).

## Water Treatment

Groundwater from the underground mine workings will be pumped to the settling pond for water storage and removal of total suspended solids. (DEIR, p. 3-17.) The settling pond will also feature an aeration system to oxygenate the water, which will precipitate (i.e., create a solid from a solution) a significant portion of dissolved iron and manganese and be removed from the settling pond approximately every 10 years. (DEIR, p. 3-17.) Water from the settling pond will then be pumped to the proposed on-site water treatment plant (WTP) and filtered to remove the remaining iron and manganese. During this process, a small dose of chemical oxidant [sodium hypochlorite (NaOCl) or potassium permanganate (KMnO4)] will be added to enhance the kinetics of the reaction under all surface conditions, such as seasonal variations. (DEIR, p. 3-17.) The first step in the WTP process is filtration through natural, mined manganese dioxide ($MnO_2$) media. (DEIR, p. 3-17.) The Project applicant chose $MnO_2$ as the primary form of treatment due to its efficient removal characteristics for iron and manganese. (DEIR, p. 3-17.) Based on the groundwater quality conditions identified above, this treatment process is sufficient to meet State discharge standards. (DEIR, p. 3-17.) However, the WTP design calls for an additional level of treatment using granular activated carbon (GAC) in the event that water quality worsens during periods of active mining. (DEIR, p. 3-17.)

The proposed treatment process will also reduce concentrations of arsenic and ammonia, both of which have been detected at low concentrations in surface seeps near the mine. (DEIR, p. 3-17.)

Arsenic is not present in levels above water quality goals in the Brunswick Shaft samples but exceeds water quality goals in the mine drains. Once mine dewatering commences the flow of water through the mine workings would be reversed from its current condition with water pumped up the New Brunswick shaft rather than the current mine drains. The elevated arsenic levels in the drain versus the New Brunswick shaft have been noted in the DEIR. (DEIR, p. 4.8-21.) Oxidized arsenic will be adsorbed by precipitated iron and then adsorbed by the $MnO_2$ filter media. The low concentrations of ammonia (NH3) will be removed by the aeration process occurring in the pond. (DEIR, p. 3-17.) As a contingency, sodium hydroxide, commonly used in water quality treatment processes to adjust pH, will be included in the State permitting efforts for the WTP should it become necessary to treat NH3 in higher concentrations than have been previously detected. (DEIR, p. 3-17.) This may occur as a result of explosives used during periods of active mining.

After the water treatment process, water will be stored in a finish water tank and will constitute the final effluent before discharge to South Fork Wolf Creek. (DEIR, p. 3-18.) The water contained in the finish tank will be pH adjusted to meet regulatory compliance standards. (DEIR, p. 3-18.) The project applicant will achieve this by adding a small amount of sulfuric acid (commonly used in municipal treatment systems) to treat the effluent as necessary. (DEIR, p. 3-18.) At the conclusion of the water treatment process, any water discharged to South Fork Wolf Creek will meet or exceed applicable water quality objectives.

## Water Quality in South Fork Wolf Creek

Contrary to some commenters' statements, any discharged treated water from the Project will exceed the water quality levels currently found in South Fork Wolf Creek. South Fork Wolf Creek is a heavily disturbed watershed and has been altered by historical land uses, including logging, hard rock and placer mining, agriculture, and construction and maintenance of road and railroad transportation networks. (Balance Hydrologics, 2020, pp. 8-9, 39.) South Fork Wolf Creek is a perennial stream that begins at a 48-inch culvert fed by surface drainage and road runoff from both the east and west sides of Brunswick Road. (DEIR, p. 4.4-3.) Samples from the creek taken in December 2018 and April 2019 detected elevated levels of iron and manganese. (DEIR, p. 4.8-23.) South Fork Wolf Creek flows west and empties into Wolf Creek, which itself is heavily disturbed and has historically included upstream discharges, such as that from the City of Grass Valley Wastewater Treatment Plant.[23] The Project will treat the groundwater currently existing in the mine to remove iron, manganese, and other elements to a level that meets or exceeds drinking water quality. The result will be that any water discharged to South Fork Wolf Creek will exceed the water quality levels currently existing within the creek, thus having a positive environmental effect on the creek, downstream users, and habitat.[24]

[23] Waste Discharge Requirements for the City of Grass Valley Wastewater Treatment Plant, Nevada County, CVRWQCB Order No. R5-2016-0012 (NPDES No. CA0079898), available at https://www.waterboards.ca.gov/rwqcb5/board_decisions/adopted_orders/nevada/r5-2016-0012.pdf.

[24] For example, surface water samples taken from South Fork Wolf Creek in April 2019 contained iron ranging from 310 µg/L to 940 µg/L and manganese ranging from 57 µg/L to 140 µg/L, depending on the location of the sample. (DEIR, 4.8-23.) The Project's proposed WTP would treat groundwater pumped from the New Brunswick shaft to concentrations of iron and manganese below 300 µg/L and 50 µg/L, respectively, which meets the screening level and effluent limits for Receiving Waters with Municipal and Domestic Supply Beneficial Use. (DEIR, Table 4.8-2.)

Contrary to the assertions of some commenters, the DEIR contains voluminous baseline surface water quality data. The baseline surface water quality data are described within Section 3.4.1.2 and presented in Tables 3.5 through 3.10 of Appendix K.2 of the DEIR. The baseline data include results from samples collected from the underground workings, from drains that discharge water from the underground workings, from Wolf Creek, and from South Fork Wolf Creek. The results include field parameters, general water chemistry parameters, and metals. In particular, Table 3-8 of Appendix K.2 contains pH, temperature, dissolved oxygen (DO), electrical conductivity, and oxidation-reduction potential (ORP) measurements from three locations along South Fork Wolf Creek and two locations on the former SPI site that discharge to South Fork Wolf Creek. Table 3-8 of Appendix K.2 presents laboratory analytical results for 18 general water chemistry parameters and 19 different metals from two samples collected along South Fork Wolf Creek at locations that will be upstream and downstream of the proposed treated water discharge location.

Table 3-10 of Appendix K.2 provides field measurements of flow, temperature, specific conductance, pH, and turbidity for two locations (upstream and downstream) along South Fork Wolf Creek measured during five different storm flow conditions, including summer baseflow, early-season post-storm (comparable to first-flush) flows, winter baseflow, rising flows during a "qualifying rain event of 1.25 inches", and peak flows during the same "qualifying rain event". Additional details regarding flow conditions and baseline water quality conditions in South Fork Wolf Creek are also provided in Appendix K.1 of the DEIR.

Further analysis of the baseline water quality data is provided in Section 3.4.2 of Appendix K.2 to the DEIR. In particular, data from South Fork Wolf Creek are presented on Figures 3-12 and 3-19 of Appendix K.2 to the DEIR, while the baseline data from the underground workings, drains, and Wolf Creek are presented on Figures 3-12 through 3-18 of Appendix K.2 to the DEIR. All the sampling described was considered as part of the evaluations conducted in the DEIR. However, future compliance with water quality standards, including parameters such as temperature, turbidity, pH, and dissolved oxygen, and also general chemistry and metals, will be based on comparison of the results from the upstream and downstream sample locations, while treated water discharge to South Fork Wolf Creek is actually taking place, and not on current baseline conditions. While the baseline sampling that has been conducted for the Project informs the analysis of potential impacts in the DEIR, it would not be relevant for future compliance once dewatering, water treatment, and discharge begin. The compliance sampling requirements would be defined in the Monitoring and Reporting Program for the NPDES permit to be issued by the Regional Water Quality Control Board.

## Regulatory Requirements

The Project applicant is undertaking extensive water treatment procedures before discharging any effluent into South Fork Wolf Creek in conformance with all legal requirements. Any discharge to South Fork Wolf Creek that does not meet certain water quality standards is prohibited by law. The state Porter-Cologne Water Quality Control act authorizes the CVRWQCB to implement certain water quality control measures. (DEIR, p. 4.8-28.) These measures are known as water quality control plans (also referred to as basin plans) for specific groundwater and surface water basins. (DEIR, p. 4.8-28.) The CVRWQCB is responsible for issuing permits that regulate activities such as stormwater, wastewater, industrial water discharge, and disturbance of wetlands. (DEIR, p. 4.8-28.) The Project applicant's discharge of treated water is expected to fall under the CVRWQCB's Limited General Threat Order (R5-2016-0076-01) as a "Tier 3" discharge. (DEIR, p. 4.8-28.) Such discharges to surface water that are greater than 250,000 gpd (greater than 175 gpm) and/or that are longer than four months are allowed if the water to be discharged

(with or without treatment) meets the applicable screening levels in the permit. (DEIR, p. 4.8-28.) To comply with this provision, the Project applicant will file a Notice of Intent (NOI) with the CVRWQCB for coverage under the Limited Threat Discharge permit, which will include a detailed description of the dewatering, treatment, and discharge components of the Project. (DEIR, p. 4.8-28.) The Project applicant will also be required to implement a Monitoring and Reporting Program to continuously monitor, sample, and report discharges as required by the Regional Board.

As the Project applicant will be legally required to meet certain water quality objectives, the applicant will determine whether the discharge from the Project to South Fork Wolf Creek will exceed the existing water quality levels of the surface water in the creek, based on water samples from the creek. Additionally, the Regional Board's permit will contain requirements that the project applicant continuously monitor and ensure that water quality objectives are met throughout the life cycle of the Project.

A Notice of Applicability (NOA) for the water discharge is required by Mitigation Measure 4.8-1(a). As stated in the mitigation measure, the owner shall be required to submit quarterly monitoring reports to the Regional Water Quality Control Board. General Order R-5-2016-0076 has been replaced with General Order R-5-2022-006 and the FEIR has been updated to reflect this change (see Chapter 3 of this Final EIR, Revisions to the DEIR Text). Upon receipt of the complete Notice of Intent (NOI), if the discharge is deemed eligible for coverage under the General Order, the CVRWQB will issue a Notice of Applicability (NOA). The NOI shall include evaluation of potential constituents of concern and demonstrate that WTP design shall successfully treat mine water to meet the water quality standards and treatment goals. The NOA will specify monitoring and reporting program requirements. All NPDES permits are required to specify requirements for recording and reporting monitoring results. General monitoring provisions of the General Order require that samples taken for the purpose of monitoring be representative of the monitored activity. Records of monitoring must be kept and maintained and reports to the CVRWCB quarterly. Any noncompliance which may endanger health or the environment must be reported orally within 24 hours from the time the Discharger becomes aware of the circumstances. A report shall also be provided within five (5) days of the time the Discharger becomes aware of the circumstances. If the discharge is not deemed eligible for coverage under the General Order, the mine operator would need to apply for project-specific waste discharge requirements to achieve water quality that meets applicable water quality standards; however, it is expected that the discharge will qualify for coverage under the General Order based on the available industry standard methods to reduce iron and manganese (and potentially ammonia and arsenic) and the existing use of the General Order for the nearby Empire Mine and North Star Mine water discharge.

A standard provision in the NOA is the duty to comply with all of the terms, requirements, and conditions of the General Order. Any noncompliance constitutes a violation of the Clean Water Act (CWA) and the California Water Code and is grounds for enforcement action; permit termination, revocation and reissuance, or modification; denial of a permit renewal application; or a combination thereof.

There are currently two other permitted discharges downstream of the Project under the same General Order. The Empire Mine State Park discharges to South Fork Wolf Creek and the North Star Water Treatment Facility discharges to Wolf Creek.

### Conclusion

As discussed in this master response and the DEIR (Chapter 4.8, Hydrology and Water Quality), the Project will construct an on-site water treatment plant that will be designed and permitted by the CVRWQCB to treat groundwater pumped from the mine to drinking water quality standards. The Project will only discharge treated groundwater to South Fork Wolf Creek. Thus, the DEIR appropriately concludes (DEIR, p. 4.8-52) that, after implementation of mitigation, the Project would result in a less than significant impact to the water quality of South Fork Wolf Creek.

## Master Response 36 - Flows in South Fork Wolf Creek

### Comments

Several commenters expressed concern for potential biological impacts resulting from dewatering the Project and the associated discharge to South Fork Wolf Creek. These concerns included water quality, erosion, and increased flows and how these changes may impact a variety of species that use this habitat area.

### Discussion

As discussed in the Project Description of the DEIR and summarized in Master Response 35, groundwater exists within the underground workings of the Project site and would be pumped out of the New Brunswick shaft into an existing clay-lined settling pond. From the clay-lined settling pond, the water will then be moved through an on-site water treatment system to meet or exceed applicable water quality objectives and then be discharged to South Fork Wolf Creek. (DEIR, p. 3-18.) Any discharge of water to South Fork Wolf Creek will be performed under a discharge permit from the Central Valley Regional Water Quality Control Board (CVRWQCB), with required monitoring and reporting, to ensure that discharge water meets all applicable water quality standards. (DEIR, p. 4.8-28.) Water will be discharged to South Fork Wolf Creek at a maximum rate of 5.6 cubic feet per second (cfs) or 2,500 gallons per minute (gpm) during the approximately 6 months of initial dewatering of the mine. After initial dewatering, groundwater is anticipated to continue to infiltrate the underground workings at a rate of approximately 1.9 cfs (850 gpm) once initial dewatering is complete and will require an ongoing dewatering program.

#### Water Quality and Erosion

The DEIR Hydrology section (DEIR Chapter 4.8) and associated technical studies (Appendix K) addressed potential impacts to the South Fork Wolf Creek stream channel that may result from discharge of treated water, including water quality and erosion. Groundwater from the underground mine workings will be pumped to the settling pond for water storage and removal of total suspended solids and iron and manganese (through an aeriation system), then to an on-site water treatment system for filtration for removal of remaining iron and manganese. (DEIR, p. 3-17.) The proposed treatment process will also reduce concentrations of arsenic and ammonia, both of which have been detected at low concentrations in surface seeps near the mine. (DEIR, p. 3-17.) At the conclusion of water treatment, water discharged to South Fork Wolf Creek will exceed the water quality levels currently existing within the creek. As a result, biological species that may utilize South Fork Wolf Creek will experience an improvement in overall water quality.

### Analysis of Potential Impacts to Species

As discussed above, for approximately 6 months during initial dewatering, water will be discharged to South Fork Wolf Creek at a rate of approximately 5.6 cfs and then reduced to approximately 1.9 cfs at the conclusion of this period for ongoing dewatering. The DEIR Hydrology section (DEIR Chapter 4.8) and associated technical studies (Appendix K) assumed the maximum discharge rate of 5.6 cfs to assess potential impacts from treated water discharge. Impact 4.4-2 addressed potential treated mine water discharge impacts to biological species, including fish, amphibians, invertebrates, and benthic macroinvertebrates (BMI) and concluded this impact would not be significant. As explained in Impact 4.4-2, and detailed in Chapter 4.8 and Appendix K.1, the proposed project will discharge a maximum of 5.6 cubic feet per second (cfs) of treated mine water to South Fork Wolf Creek. Base flow in South Fork Wolf Creek may range from 0.17 cfs in the summer to 6.5 cfs in the winter between storm events. Sediment pebble count analysis (see Appendix K.1) indicates that the flow rate at which sediment within the channel may become mobilized ranges from 20 cfs to 90 cfs. With the addition of the maximum proposed discharge of 5.6 cfs and increasing measured baseflows by a 50 percent safety factor, post-project baseflows during non-storm periods would be expected to range between approximately 5.8 cfs and 15 cfs. These estimates are less than 23 cfs, the threshold for bedload sediment mobility and well below flows that commonly exhibit significant work on the channel (i.e., 1- to 2-year flood).

### Conclusion

The DEIR therefore concludes potential downstream water quality and erosion impacts to the stream channel and associated riparian zone along both sides of South Fork Wolf Creek from the additional discharge of 5.6 cfs would be minimal on sensitive biological resources, and do not represent a significant impact to the stream channel or associated riparian zone within South Fork Wolf Creek.

## Master Response 37 - Birds and Raptors

### Comments

Several comment letters asserted that the DEIR did not evaluate certain protected bird species having the potential to occur in the project area and mischaracterized the California black rail. The bird species that the commenters allege are not evaluated in the DEIR include willow flycatcher, olive-sided flycatcher, yellow-breasted chat, yellow warbler, and California spotted owl. Many commenters also allege that the bird surveys performed for the Project were not appropriately timed.

### Discussion

The Project site was studied for special-status and protected birds, and raptors as part of the Biological Reconnaissance Surveys (BRA) conducted in 2018 and 2019. These surveys were conducted to determine whether special-status species protected under the federal Endangered Species Act (ESA), California Endangered Species Act (CESA), or the Migratory Bird Treaty Act, are present or have the potential to be present on-site due to suitable habitat. Reconnaissance level biological resources field surveys were conducted on foot for the Brunswick Site and Centennial Site on December 9th through 12th and 17th and 18th, 2018. Follow-up reconnaissance level biological resources field surveys were conducted for potential special-status wildlife species habitats on December 30th, 2018 for both sites. Reconnaissance-level wildlife surveys were conducted on July 10th and 14th, 2019 for the Centennial Site and July 14th and 16th, 2019 for the Brunswick Site, to document the presence and/or suitable habitat for special-status wildlife species.

As summarized in DEIR section 4.4.2 and Appendix F, only two special-status bird species have the potential to occur onsite: Cooper's hawk and California black rail. None of these species were identified during the BRA site visits and are considered to have a low potential to occur within the Project site except for Cooper's hawk, which has a moderate potential to occur within the project site. In addition, the DEIR and Appendix F, identified the potential for nesting raptors and other migratory bird species to occur within the Project site.

Impact 4.4-2 in the DEIR addressed potential impacts to California black rail and non-special status birds protected by other laws (e.g., Migratory Bird Treaty Act). As detailed in Impact 4.4-2, the potential for California black rail to occur onsite is low. Despite this low potential for onsite occurrence, the DEIR conservatively concluded that the Project would cause a potential impact to this species and therefore the DEIR required mitigation. The potential for non-special status birds and raptors on-site is high and considered a potentially significant impact, which also includes the potential for Cooper's hawk to occur and nest within the Project site. Mitigation measures for potential impacts to all bird and raptor species require pre-construction surveys prior to surface disturbance and avoidance and minimization measures if any of these species are identified during the preconstruction survey. These mitigation measures reduce the impact to a less than significant level. Note that the DEIR reflected that California black rail is California Threatened, but it is also considered California Fully Protected. Even though no new impact has been identified, the DEIR has been amended to reflect the Fully Protected status for this species (see Chapter 3 of this Final EIR, Revisions to the Draft EIR Text). Additionally, Mitigation Measure 4.4-2(d) has been amended to remove reference to an ITP being obtained for take of California black rail. As this species is considered to have a very low potential to be found on-site, surveys will be conducted prior to site disturbance, and consultation with CDFW and avoidance shall be required in the case of species presence, this impact is still considered less than significant.

## Riparian Bird Species

A more recent CNDDB search was conducted in May 2022 and identified a recently reported occurrence of the yellow-breasted chat within the 5-mile search radius of the Project site. According to the California Department of Fish and Wildlife CNDDB Occurrence Report, the yellow-breasted chat was observed July 2021 within the 5-mile search radius of the Project site. Only the yellow-breasted chat and California spotted owl (see below) has been mapped in the CNDDB within 5 miles of the Project site. The yellow-breasted chat occurrence was mapped along the South Fork Wolf Creek, approximately 1.5 miles downstream of the Brunswick culvert outlet where South Fork Wolf Creek daylights within the Brunswick Site. The yellow-breasted chat is a CDFW Species of Special Concern and is not State or federally listed. This species CNDDB mapped location is within the Empire Mine State Historic Park and within an area referred to as the Bennett Street Grasslands. This species was not identified within any of the Project areas during surveys conducted between December 2018 and August 2020.

If the yellow-breasted chat were to be found on-site, it would most likely be found within the riparian areas of the Project site. As discussed above, nesting raptors and other migratory bird species were analyzed and identified as a potential impact. Mitigation Measure 4.4-2(g) requires a pre-construction survey for bird species prior to surface disturbance and avoidance and minimization measures in the event a species is identified. Therefore, the potential impact to this species has been analyzed and addressed in the DEIR. Nevertheless, for clarity, this Final EIR includes revisions to Chapter 4.4, Biological Resources, to include discussion of yellow-breasted chat and other riparian bird species discussed below, and as shown below, targeted revisions have been made to Mitigation Measure 4.4-2(g) to reference this species. Willow flycatcher, olive-sided flycatcher, and yellow warbler have not been mapped within the CNDDB within 5 miles of the Project site. However, an updated CNDDB 9 Quad Species List review of the Project site

within the Grass Valley Quad being the central quad in the 9 Quad Species review does list those three species as "unprocessed" under data status. The CNDDB 9 Quad Species List was generated on April 20, 2022. Per CDFW, "unprocessed CNDDB data is data that has been submitted to the CNDDB but has not yet been entered into the CNDDB occurrence database and GIS. A bibliographic record has been created for this data with quad and county information, but a thorough review of the information has not yet been conducted. Unprocessed records should be used with caution as they have not been quality controlled. These data will eventually be reviewed by a CNDDB Program biologist and incorporated into the CNDDB occurrence database and GIS if appropriate." These species are most likely to occur within riparian areas where quality habitat for these species occurs. Habitat for these species within the Project site is considered limited given the level of disturbance within the Project site. More developed and less disturbed riparian habitat is located outside of the Project site along South Fork Wolf Creek within the Bennett Street Grasslands where the yellow-breasted chat is mapped within the CNDDB. The riparian habitat within the Centennial and Brunswick Industrial Sites provides minimal suitable habitat for any of these species given the level of disturbance historically within those areas as well as the recent disturbance within both areas in 2021 related to a fire that burned a large area within the Centennial Area and a large storm in late December 2021 that heavily impacted the riparian habitat along the South Fork Wolf Creek within the Brunswick Area. These species were not identified within the Project site during surveys conducted between December 2018 and August 2020. Accordingly, these species have a low probability of occurrence on-site, and no potential impact is expected. In addition, as discussed above, nesting raptors and other migratory bird species were analyzed and identified as a potential impact and mitigation is required for these potential impacts in the DEIR. Although no new impact has been identified, for clarification purposes, Mitigation Measure 4.4-2(g) is hereby revised in this Final EIR (as shown below) to include, by name, the above-discussed riparian bird species.

## California Spotted Owl

In response to several public comments about the known presence of California spotted owl within Empire Mine State Park, and information available on the Biogeographic Information and Observation System (BIOS) managed by CDFW, the Final EIR includes specific discussion of the California spotted owl (CSO) species (see Chapter 3 of this Final EIR, Revisions to the DEIR Text). The California spotted owl is not listed as threatened or endangered in the federal Endangered Species Act (ESA) or the California State Endangered Species Act (CESA) but is rather referred to as a Species of Special Concern by CDFW, which do not require take permits for incidental take, but do require analysis under CEQA. The DEIR acknowledges that raptor nests and eggs are protected by Section 3503.5 of the California FGC, which states, "It is unlawful to take, possess, or destroy any birds in the order *Falconiformes* or *Strigiformes* (birds-of-prey) or to take, possess, or destroy the nest or eggs of any such bird except as otherwise provided by the code or any regulation adopted pursuant thereto." Notably, the DEIR also acknowledged that the Brunswick Site has suitable habitat for raptors (owls are a type of raptor) and included mitigation specifically for raptor and nesting bird species. (see Mitigation Measure 4.4-2(g).)

As identified in the BIOS database, a CSO nest was documented within the Brunswick Area in 2011. Three additional follow up surveys in 2012, 2016 and 2018 did not document the presence of a nest but did document the presence of a pair of CSO (in 2012 and 2016) and a single male CSO in 2018. Based on the information from BIOS, and to clarify the analysis provided in the DEIR on impacts to raptors, two surveys for presence and nesting status of California spotted owl were conducted by a qualified biologist pursuant to the United States Forest Service (USFS) protocol (1992) on the Brunswick Site. California spotted owl callback surveys were conducted at two locations within the Brunswick Area on August 5, 2022 and then again on August 11, 2022. No

CSO responded to any of the calls from either survey station either night (Please see Appendix I to this Final EIR for the Technical Memorandum for the Idaho-Maryland Mine Project – Brunswick Area California Spotted Owl Surveys and Assessment, August 2022).

Given the information obtained via BIOS 6, identifying four previous sightings of CSO on the Brunswick Site, Table 4.4-6 in the DEIR has been updated in Section 4.4 of the FEIR to include California spotted owl by name, and to indicate that the potential for CSO nesting onsite is Moderate, while potential for presence of transitory CSO onsite is High (please see Response to Comment Grp 31-10 and Chapter 3 of this Final EIR, Revisions to the Draft EIR Text). Although CSO was seen on-site most recently in 2018, it was a single male bird, not a nest or breeding pair; thus, it would not be protected by the Fish & Game Code's prohibition of disturbing eggs or nests. A nest has not been seen on-site since 2011. Further, the two protocol surveys conducted in 2022 did not identify any CSO on-site.

Although no new impact has been identified, Mitigation Measure 4.4-2(g) has been amended as shown below. In addition, for clarification purposes, Mitigation Measure 4.4-2(g) is hereby revised in this Final EIR to include, by name, the above-discussed riparian bird species:

*~~Non-Special Status Raptors and Migratory~~ Nesting Birds*

*4.4-2(g)* *Pre-construction Survey and Avoidance and Minimization Measures. Prior to initiation of ground-disturbing activities for any phase of project construction, if construction is expected to occur during the raptor nesting season (February 1 to August 31), a qualified biologist shall conduct a preconstruction survey prior to vegetation removal, including one daytime survey and one nighttime survey targeted at California spotted owl, consistent with the USFWS (1992) California spotted owl survey protocol. The pre-construction survey shall be conducted within 7 days prior to commencement of ground-disturbing activities. The survey shall be conducted within all areas of proposed disturbance and all accessible areas within 250 feet of proposed disturbance. If the pre-construction survey does not show evidence of active nests, a letter report documenting the results of the survey shall be provided to the Nevada County Planning Department, and additional measures are not required. If construction does not commence within 7 days of the pre-construction survey, or halts for more than 14 days, an additional pre-construction survey shall be required. Removal of any trees within the Brunswick Area would occur between September 1st and January 31st to ensure that no nesting birds, raptors, or owls would be impacted by the proposed IMM project.*

*If any active nests are located within the proposed disturbance area, including active nests within riparian habitat for the yellow-breasted chat, willow flycatcher, yellow warbler, and olive-sided flycatcher, an appropriate buffer zone shall be established around the nests, as determined by the project biologist. The biologist shall mark the buffer zone with construction tape or pin flags and maintain the buffer zone until the end of breeding season or the young have successfully fledged. Buffer zones are typically 100 feet for migratory bird nests and 500 feet for raptor nests. If active nests are found within the disturbance footprint, a qualified biologist shall monitor nests weekly during construction to evaluate potential nesting disturbance by construction activities. Guidance from CDFW shall be required if establishing the typical buffer zone is impractical and/or the willow flycatcher, a State listed species, is documented nesting during the pre-construction surveys for nesting birds. Additionally, an ITP could be required by CDFW if complete avoidance of willow flycatcher is*

> *not feasible. If construction activities cause the nesting bird(s) to vocalize, make defensive flights at intruders, get up from a brooding position, or fly off the nest, then the exclusionary buffer shall be increased, as determined by the qualified biologist, such that activities are far enough from the nest to stop the agitated behavior. The exclusionary buffer shall remain in place until the young have fledged or as otherwise determined by a qualified biologist.*

Per CDFW, an analysis of project level impacts to Species of Special Concern typically includes analysis of "population-level effects, proportion of the taxon's range affected by a project, regional effects, and impacts to habitat features." Population-level and regional effects to CSO are not expected, given that CSO prefer older, closed canopy forests and forages for prey that require woody debris and understory vegetation for cover, and the Project site does not include this optimal type of CSO habitat. Further, the 18.7 acres of trees being removed from the Brunswick Site are a very small proportion of the range of a single CSO, which can range from 946 to 1,520 acres in the Tahoe National Forest (see Roberts 2017), and an even smaller percentage of the overall range of CSO species along the western slope of the Sierra Nevada, in the southern Coast Ranges from Monterey County to Santa Barbara County, and in the Traverse and Peninsular Ranges from southern California to Baja California. Moreover, while 18.7 acres of trees will be removed from the Brunswick Area, the impacts to overall habitat features are considered minimal, given that the Project sites do not include optimal CSO habitat, and the provided mitigation measure will ensure protection for any nesting pairs. The Centennial Site has younger trees than the Brunswick Site and does not contain suitable habitat for CSO. As such, given the negative results from recent surveys and the time that has passed since a prior nest sighting in 2011, the DEIR's conclusion that a less than significant impact to raptors and nesting birds (including CSO) would occur with implementation of mitigation remains appropriate.

### Timing of Bird Surveys

Some commenters asserted that wildlife surveys were not conducted at the appropriate time of year, and not in conformance with CDFG or USFWS protocols. However, protocol-level surveys are not required for CEQA analysis. Moreover, many surveys were conducted during the appropriate time of year, as set forth in relevant survey protocols, to detect presence of the relevant wildlife species. As an example, the 2003 CDFW protocol for willow flycatcher calls for a survey during the period of June 15 to June 25, and a second survey either between June 1 and June 14, or between June 26 and July 15. Reconnaissance surveys were conducted at both sites on July 14th, which is within one of the protocol survey windows, even though protocol level surveys are not required. Moreover, Mitigation Measure 4.4-2(g) requires pre-construction surveys for willow flycatcher, which will ensure that impacts to willow flycatcher nests are avoided.

While the reconnaissance level surveys conducted on July 10th and 14th 2019 for the Centennial Site and July 14th and 16th for the Brunswick Site may not fall within the survey protocol recommended windows for all species, protocol-level surveys are not required for CEQA analysis. Rather, the survey results along with review of CNDDB records and appropriate mitigation measures including pre-construction surveys was relied on to appropriately reach the conclusion that impacts to wildlife species is less than significant after mitigation. As protocol-level surveys are not required, and the DEIR requires pre-construction surveys, the selected survey dates are appropriate for purposes of CEQA analysis.

## Conclusion

This master response confirms that the DEIR identifies the Project could result in a significant impact to nesting raptors and other migratory bird species, and thus, includes Mitigation Measure

4.4-2(g) requiring a pre-construction survey for nesting raptors and migratory bird species prior to surface disturbance and avoidance and minimization measures in the event a species is identified. Thus, no new significant impact has been identified and the mitigation in the DEIR is protective of the bird species identified by the commenters as being missed in the DEIR. Nevertheless, for clarity, Mitigation Measure 4.4-2(g) has been revised to reference the species identified by the commenters, including yellow-breasted chat, willow flycatcher, yellow warbler, and olive-sided flycatcher and California spotted owl, and provide additional details regarding survey methodology.

## Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog

### Comments

Several commenters asserted that the DEIR incorrectly concluded that foothill yellow-legged frog and California red-legged frog have a very low potential to occur within the Centennial and Brunswick Sites (i.e., Project site). Many commenters also claimed that the visual encounter surveys performed for foothill yellow-legged frog was not conducted during the optimal time of year.

### Discussion

As explained in Master Response 30 (Biological Study Technical Adequacy), significant technical study was undertaken of the Project site, including review of site conditions for special-status amphibians. As part of the Biological Resources Assessment (BRA), the site was surveyed and analyzed for potential California Red-Legged Frog (CRLF) and Foothill Yellow-Legged Frog (FYLF) habitat. The BRA did not identify FYLF or CRLF on-site and found that only marginal habitat existed for these species on the Project site. This analysis, and its conclusions, were peer reviewed by the County's biological consultant and summarized in DEIR section 4.4.2 and Impact 4.4-2.

DEIR section 4.4.2 and Impact 4.4-2 explain that neither CRLF or FYLF have been previously identified within the Wolf Creek watersheds and the likelihood of either of these species being present within the project areas was considered very low (see DEIR Table 4.4-6).

Regarding the CRLF, no Designated Critical Habitat (DCH) has been mapped for CRLF on the project site and the species has not been identified within 5 miles of the project site. CRLF require suitable breeding locations be located within 1.25 miles of each other and connected by barrier-free dispersal habitat that is at least 300 feet in width (USFWS Region 1 CRLF Recovery Plan dated May 28, 2002). It is unknown whether suitable breeding locations are located within 1.25 miles of the project site; however, the areas surrounding the project site contain busy roads, industrial, commercial, and residential development, and the ponds within the project site do not connect with barrier-free dispersal habitat that is a minimum of 300 feet wide. Additionally, given that CRLF have not been identified in the Grass Valley USGS Quadrangle, the watershed associated with the project area, or within 5 miles of the Brunswick Site, the potential for this species to occur is considered very low.

Despite the very low likelihood CRLF may be present on-site, the DEIR conservatively concluded a potential impact could occur and required preconstruction surveys for CRLF. With the implementation of this mitigation measure, the CRLF would be avoided and fully mitigated. Furthermore, given the impacts to Clean Water Act regulated "waters of the U.S.," including wetlands, a Section 7 consultation with the USFWS will be required. The pre-construction surveys and monitoring outlined within the DEIR for CRLF are comprehensive and provide measures to

further minimize potential impacts to CRLF. In addition, the pre-construction survey and monitoring methodologies would follow the recommendations made by the USFWS as part of any Section 7 consultation process for this species.

There are several occurrences of FYLF within 5 miles of the project site. The nearest occurrence of FYLF is located along Deer Creek, approximately 3 miles north of the Centennial Site. The occurrence consists of a single FYLF observed in Deer Creek in 1903 and the species is considered extirpated from Deer Creek (CNDDB 2022). The nearest FYLF occurrence to the Brunswick Site is located approximately 3 miles to the east/southeast in Greenhorn Creek. This occurrence is considered extant.

Visual Encounter Surveys (VES) for FYLF were conducted August 29, 2019 within South Fork Wolf Creek. The FYLF VES surveys were conducted during the periods identified by CDFW as the most accurate for detecting species presence, per the CDFW Considerations for Conserving the FYLF document (dated May 14, 2018). As stated within the CDFW document, "current scientific literature suggests surveys for presence will be most accurate if conducted during and immediately following the breeding season (spring-summer)" and they recommended VES methods to be employed to determine an accurate survey result for the species. In addition, following release of the DEIR, additional FYLF VES surveys were conducted on June 8th and June 15th 2022 (see Appendix J to this Final EIR for a survey memo). The June 2022 VES surveys did not identify FYLF and confirmed marginal suitable habitat as explained in the DEIR and summarized below. The additional FYLF VES surveys conducted in June 2022 included surveys within three survey stretches similar to the survey locations conducted in August 2019 for FYLF; however, the June 2022 FYLF surveys included the entire stretch of South Fork Wolf Creek within the Bennett Street Grasslands and where 2 of the 3 electrofishing locations surveyed by CDFW on March 8, 2022 are located.

In its comment letter (see Agency Letter 3 of this Final EIR), CDFW suggested additional surveys under the CDFW Considerations for Conserving the FYLF document, but acknowledged that no approved survey protocols exist for FYLF. CDFW noted that surveys in the late summer are often the easiest method to determine presence, and that to increase likelihood of detection, surveys should include one VES in April-June. The applicant already conducted a survey in June and then one in August, so the applicant has already complied with most of what CDFW is suggesting – even though what it is suggesting is not mandatory. The surveys conducted are sufficient to detect presence for CEQA purposes, and protocol level surveys (such as the suggested survey schedule in the CDFW Considerations for Conserving the FYLF) are not required for CEQA. Moreover, Mitigation Measure 4.4-2(a) requires pre-construction surveys that would detect species presence prior to disturbance, to ensure avoidance of impacts to this species.

The CDFW electrofishing surveys identified two non-native fish species (brown trout and bluegill) and no additional fish or amphibian species during the survey. CDFW concluded that the two survey locations furthest away from the Brunswick Site had the greatest densities of fish with better health conditions than the survey location located closest to the Brunswick Site.

As summarized in DEIR Impact 4.4-2 and Appendix F, FYLF was not identified within South Fork Wolf Creek from the outlet of South Fork Wolf Creek within the Brunswick project area during the summer 2019 VES surveys conducted. As discussed above, the species has not been previously identified within the Wolf Creek watershed and was not identified within South Fork Wolf Creek during FYLF VES surveys implemented in August 2020 and June 2022. These surveys were conducted by two qualified biologists with extensive experience conducting amphibian and FYLF VES surveys. In addition, the area near the project site only includes marginal suitable habitat for

the species downstream towards the City of Grass Valley within a small area of the Empire Mine State Historic Park and, as a result, the species has a very low likelihood of being present within South Fork Wolf Creek or the Wolf Creek watershed, given the lack of suitable habitat for the species, except for a very small stretch of the creek between the Brunswick Site and the City of Grass Valley. Suitable habitat is lacking due to the high levels of current and historical disturbance within South Fork Wolf Creek within and downstream of the Brunswick Site. Despite this low likelihood of potential occurrence, the DEIR concluded a significant impact to FYLF habitat may occur and provided Mitigation Measure 4.4-2(a) requiring pre-construction VES surveys (following the CDFW 2018 Considerations for Conserving the FYLF) prior to any proposed disturbance and changes in discharges within South Fork Wolf Creek. Implementation of this mitigation measure reduces the potential impact to a less than significant level, if FYLF were to be documented within South Fork Wolf Creek during the implementation of the pre-construction VES surveys for FYLF.

### Conclusion

Based on extensive scientific investigation (e.g., literature review, site surveys), the DEIR appropriately concluded that there is a very low likelihood for CRLF and FYLF to occur on the Centennial and Brunswick Sites. Nevertheless, out of an abundance of caution, the DEIR conservatively concluded the project could have a significant impact to these species, and thus, included Mitigation Measures 4.4-2(a) (FYLF) and 4.4-2(c) (CRLF) setting forth avoidance and minimization measures to ensure protection of the species.

## 2.3 RESPONSES TO COMMENTS

Each comment letter received has been numbered at the top and bracketed to indicate how the letter has been divided into individual comments. Each comment is given a number with the letter number appearing first, followed by the comment number. As noted above, for efficiency and clarity, the comment letters have been organized into 10 distinct categories: Agency Letters; Group Letters; Form Letter A; Form Letter B; Form Letter C; Form Letter D; Support Cards; Individual Letters; Late Letters; and DEIR Meeting. Therefore, the letter number will correspond to the category (i.e., the first agency letter would be numbered Agency Letter 1), and the first comment in Agency Letter 1 would have the following format: Agcy 1-1. For further example and clarification, the first comment in Group Letter 1 would be numbered Grp 1-1; the first comment in Form Letter A 1 would be A 1-1; the first comment in Form Letter B 1 would be B 1-1; the first comment in Form Letter C 1 would be C 1-1; the first comment in Form Letter D would be D 1-1; the first comment in Support Card 1 would be Sup 1-1; the first comment in Individual Letter 1 would be Ind 1-1; the first comment in Late Letter 1 would be Lt 1-1; and the first comment in the DEIR Meeting transcript would be Meet-1. The response to each comment references the comment number.

Similar to the Master Responses above, the responses to the comment letters amplify or clarify information provided in the DEIR and/or refer the reader to the appropriate place in the document where the requested information can be found. Where revisions to the DEIR text are required in response to the comments, such revisions are noted in the response to the comment, and are also listed in Chapter 3 of this Final EIR. All new text is shown as <u>double underlined</u> and deleted text is shown as ~~struck through~~.

As stated above, the changes to the analysis contained in the DEIR represent only minor clarifications/amplifications and do not constitute significant new information. In accordance with

CEQA Guidelines, Section 15088.5, recirculation of the DEIR is not required, as discussed in detail in Chapter 1 of this Final EIR.

**Subject: Draft Environmental Impact Report for the Idaho-Maryland Mine Project, State Clearinghouse # 2020070378**

**Dear Mr. Kelley,**

The California Department of Parks and Recreation, or California State Parks (CSP), as it is familiarly called, welcomes the opportunity to comment on the Draft Environmental Impact Report, State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project. CDPR is a State Agency as defined by the California Environmental Quality Act (CEQA) § 21082.1, and a Trustee Agency as used by CEQA, its Guidelines, and as defined by CCR § 15386 for the resources affected by this project within a unit of the State Park System.

The mission statement and the Department Operations Manual directs CDPR to: preserve and protect biodiversity and fully functioning natural ecosystems; provide for the health and safety of the public (park visitors, park employees, and park residents); create and maintain outdoor recreation opportunities for residents and visitors of California; and protect cultural resources (http://www.parks.ca.gov/?page_id=91). The following comments reflect the internal policies and directives of CDPR as they relate to the Draft Environmental Impact Report for the Idaho-Maryland Mine Project (the Project).

**Agcy 1-1**

CDPR owns and operates Empire Mine State Historic Park (the Park) in Grass Valley, CA. The Park hosts over 100,000 visitors annually, of which at least 50,000 use the vast trail system. Empire Mine SHP is located nearby to both the Brunswick and the Centennial Project sites of the Idaho Maryland Mine. The northwest boundary of the Union Hill area of the Park is just 450 feet to the southwest of the Brunswick facility project boundary, and the Upper Union Hill Trail Loop is located 850 feet away. The main processing areas at Brunswick are less than 0.5 miles away from a large area of Union Hill, including trails and valuable wildlife habitat.

The Park contains the "Bennett Street Grasslands," which are located along East Bennett Road, a 33-acre assemblage of dense riparian areas, wetlands, and unique, low elevation wet and dry grassland communities. The Bennett Street Grasslands contain a 0.45-mile stretch of South Fork Wolf Creek. The Bennett Street Grasslands provide important breeding, wintering, and fall migration habitat for birds. Over 80 species have been detected at the site; this includes the banding and capture of the Willow Flycatcher, *Empidonax traillii* (California State Endangered Species), the yellow breasted chat, *Icteria virens* (California Bird Species of Special Concern), and detections of Olive-sided Flycatcher, *Contopus cooperi* (California State Bird Species of Special Concern) as well as, Yellow Warbler, *Setophaga petechia* (California State Bird Species of Special Concern), from 2019-2021.

The Bennett Street Grasslands and the South Fork Wolf Creek are also the site of a recently completed six-year mitigation project, the "Magenta Drain Mitigation" project which was a required mitigation from **Section A.8 of Streambed Alteration Agreement and Major Amendment No. 1600-2011-0009-R2**. The mitigation restored both wetland and riparian habitats along the South Fork Wolf Creek and included several local school groups planting native riparian vegetation along the banks of the creek.

The Bennett Street Grasslands hosts annual field trips for local 4th and 5th grade students. These students participate in active resource restoration and with the volunteer bird banding and inventory project taking place along the South Fork Wolf Creek. One such field trip was captured in the video "Bird Banding at Empire Mine State Historic Park" and featured in the 2019 Wild and Scenic Film Festival: https://youtu.be/3kJ68T92Flw. Bird banding is handled by Allison Nelson and Gold Country Avian Studies under a 7-acre conservation easement with the Bear Yuba Land Trust that is held at the Grasslands.

The Park also contains an additional portion of the South Fork Wolf Creek that is both upstream of the Bennett Street Grasslands, and downstream of the Brunswick facility, albeit much closer, familiarly called the "Upstream Reach". The "Upstream Reach" is 0.4 miles (2200 feet) downstream of Brunswick facility on South Fork Wolf Creek, 1470 feet south of the Centennial site, and holds 13 acres of valuable riparian habitat. CSP requests that it be noted that an undisturbed, historic "sulphurette works" currently located at this site.

**General Comments:**

Agcy 1-2

CSP has several significant concerns regarding the Draft Environmental Impact Report (DEIR), it's impacts, mitigations, and the Project as proposed within, as currently stated. Water quantity and quality, air quality, noise and vibration, hazardous materials, and wildfire dangers are all crucial issues for CSP, and we find the DEIR to be inadequate in mitigations, and several sections are unclear as to what the potential impacts may be. Cumulatively and individually, these potentially significant issues could negatively affect the natural resources, recreational values, health and safety of Park visitors and employees, and the general well-being of Empire Mine State Historic Park (SHP).

Water / Dewatering / Downstream Impacts

Agcy 1-3

Specifically, CSP believes the Project as well as it's impacts and mitigations fail to adequately protect the South Fork Wolf Creek, it's riparian ecosystem, and it's "Beneficial Uses." The proposal to add up to 5.6 cubic feet per second (cfs) of water from mine de-watering actions to this small fragile stream and associated riparian areas for the next 80 years, is of major concern. The South Fork Wolf Creek flows downstream from the Project through two stretches, totaling 0.64 linear miles owned by Empire Mine State Historic Park, one of which is only 0.4 miles (2200 feet) downstream of the Brunswick facility.

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

CA Water Code § 13050 section (f) states: "'**Beneficial uses**' of the waters of the state that may be protected against quality degradation include … preservation and enhancement of fish, wildlife, and other aquatic resources or preserves". The Central Valley Regional Water Quality Control Board have established in their 2018, Sacramento and San Juaquin Basin Plan that "**Fish, plants, and other wildlife, as well as humans, use water beneficially"** (page 2-1, Beneficial Uses, California Regional Water Quality Control Board, Central Valley Region, (RWQCB), 2018), and that existing "Beneficial Uses" of the Bear River Watershed which includes South Fork Wolf Creek are "Wildlife Habitat" and "Cold and Warm Freshwater Habitat" (page 2-10, RWQCB).

CDPR believes the project proposal and DEIR conflict with Nevada County General Plan, Volume 1 Goals, Objectives, Policies, & Implementation Measures, Chapter 17: Mineral Management Element, Policy 17.11: "Recognize the importance of water conservation and quality for the present and future needs of the County by: 3. Requiring that any increase or decrease of off-site discharge **is not detrimental to the downstream environment or downstream water users**." The increase in off-site water discharge from the Project to South Fork Wolf Creek could be extremely detrimental to the downstream environment and water users, of which include wildlife and riparian trees.

Specifically, the proposal to add 1.9-5.6 cfs from the Project to the South Fork Wolf Creek threatens to drastically alter the immediate riparian ecosystem with unpredictable and fluctuating water levels at any season. This could lead to changes in existing riparian tree health, unknown alterations of adjacent plant communities (including recent native tree and shrub plantings), a decrease in benthic macroinvertebrate populations, erosion and degradation of bank stability, chances of increased heavy metals, increases in turbidity, and degradation of aquatic wildlife habitat, especially for amphibians.

Air Quality and Noise / Vibration Impacts

**Agcy 1-4**

While the DEIR has focused air quality, noise, and vibration impacts on surrounding residential areas, it has failed to mention the close proximity of Empire Mine SHP, and the potential hazards for its Park trail users and employees. The Park, the natural resources contained within and its recreational users, have been neglected to be considered a "**Sensitive Receptor**" regarding Air Quality and Noise impacts. The definition of *Sensitive Receptors* in *Chapter 4.3 – Air Quality, Greenhouse Gas Emissions, and Energy, Page 4.3* neglects to include "parks and playgrounds," thereby failing to assess potential impacts to recreational users of the Park from air quality impacts. The popular Union Hill Trail Loop is just 850 feet away from the Brunswick facility and the Bennett Street Grasslands is only 900 feet south of the Centennial facility. The entire DEIR also fails to discuss how close Sensitive receptors should be to warrant analysis. Guidance from other reputable CEQA documents and air quality districts find a distance of at least 1000 feet or more when finding and analyzing Sensitive receptors.

An example of a more applicable "**Sensitive Receptors**" definition is from: *Hidden Falls Regional Park Trail Expansion Subsequent DEIR, Chapter 9, Air Quality (2020), Page 9-12*, https://www.placerair.org/DocumentCenter/View/42743/Chapter-9---Air-Quality-PDF):

3

"9.2.4 SENSITIVE RECEPTORS Some land uses are considered more sensitive to air pollution than others, because of the types of population groups or activities involved. Children, pregnant women, the elderly, those with existing health conditions, and athletes or others who engage in frequent exercise are especially vulnerable to the effects of air pollution. Accordingly, land uses that are typically considered **sensitive receptors** include schools, daycare centers, **parks** and playgrounds, and medical facilities. Residential areas are considered sensitive to air pollution because residents (including children and the elderly) tend to be at home for extended periods of time, resulting in sustained exposure to the pollutants present. **Recreational land uses are considered moderately sensitive to air pollution. Exercise places a high demand on respiratory functions, which can be impaired by air pollution, even though exposure periods during exercise are generally short. In addition, noticeable air pollution can detract from the enjoyment of recreation."**

**Agcy 1-5**

Empire Mine SHP is mentioned twenty times in the complete DEIR, but with only one reference to the close proximity of the Park to the Project in *Chapter 4.11 – Public Services and Utilities*. *Chapter 4.4 – Biological Resources* mentions Empire Mine SHP only four times: Three occurrences stem from documentation of the Foothill Yellow Legged Frog survey under the *Reconnaissance Level Biological Resources Field Surveys* section when contract biologist Greg Matuzak surveyed an unknown section of South Fork Wolf Creek on Park property one time on August 29, 2019 (without Park knowledge or a valid State Scientific Collection Permit). Empire Mine SHP is not mentioned at any point during discussions of hydrological impacts due to mine de-watering even though CSP owns a large section of the free-flowing stretch of South Fork Wolf Creek downstream of the Project. The Park location and boundaries are also lacking from all maps within the DEIR, aside from *Figure 4.8-9, South Fork Wolf Creek Reaches in Project Vicinity*, which shows an older incorrect boundary of Empire Mine SHP from a USGS topo map. CSP sent in a comment letter for the Notice of Preparation for this DEIR and it is surprising and unfortunate that very few of our concerns were addressed.

Since discussions of the proximity of the Park to the Project are virtually non-existent in the DEIR, CSP would like to encourage remedying this mistake. Environmental review by Nevada County, State Agencies and the local community are entitled to know that Empire Mine SHP is a neighbor to this potential project and that any potential impacts would affect this important community resource. All relevant maps and documents need to discuss and display the close proximity of the Park with ownership by a State Agency focused on resource protection and outdoor recreation. These sections would include:

- 3.2 Project Location
- 3.5 Project Setting and Surrounding Land Uses
- 4.3 Air Quality and Greenhouse Gas Emissions
- 4.4 Biological Resources
- 4.7 Hazards and Hazardous Materials
- 4.8 Hydrology and Water Quality
- 4.10 Noise and Vibration
- 4.13 Wildfire

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

Several maps are attached to these comments displaying location of Empire Mine SHP to both Project sites and relevant distances. Park boundaries can also be found on Page 8 of the Empire Mine State Historic Park brochure available here: https://www.parks.ca.gov/pages/499/files/EmpireMineSHPWebLayout2016.pdf

The health and safety of Park visitors and employees, the Park visitor experience, and the preservation of natural and cultural resources are of the utmost importance to California State Parks. The Project as proposed could have significant impacts on those resources and values.

If any of our comments need clarification, please do not hesitate to contact Parks Environmental Scientist Daniel Lubin at dan.lubin@parks.ca.gov or at (530) 272-0298.

Sincerely,

Daniel Lubin, Environmental Scientist
Sierra District of California State Parks

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

**Comments:**

The following sections and bullet points detail CSP points of concerns with project components, impacts and mitigations from the Idaho-Maryland Mine Project Draft EIR Volume I (Draft EIR Chapters 1-8), and may include references to the Appendices:

***Chapter 4.3 – Air Quality, Greenhouse Gas Emissions, and Energy***

Agcy 1-6

- *Sensitive Receptors, Page 4.3-11*

  The definition of "Sensitive Receptors" has omitted the important category of "Parks and Playgrounds" in this paragraph and in numerous following sub-sections, and in *Appendix E.1, Health Risk Assessment*. CSP requests that "Parks and Playgrounds" be added to this definition as a "Sensitive Receptor," especially considering the numerous air pollutants theorized to be generated by the Project, the proximity of Empire Mine State Historic Park, and the guidance found in many relevant CEQA documents. The *San Joaquin Valley Unified Air Pollution Control District Final Draft Guidance for Assessing and Mitigating Air Quality Impacts February 19, 2015* (page 10) (https://www.valleyair.org/transportation/GAMAQI-2015/FINAL-DRAFT-GAMAQI.PDF) states:

  "Sensitive Receptors: People that have an increased sensitivity to air pollution or environmental contaminants. **Sensitive receptor locations include** schools, **parks** and playgrounds, day care centers, nursing homes, hospitals, and residential dwelling unit(s). **The location of sensitive receptors is needed to assess toxic impacts on public health**."

  The *CEQA Air Quality Handbook A GUIDE FOR ASSESSING THE AIR QUALITY IMPACTS FOR PROJECTS SUBJECT TO CEQA REVIEW (San Luis Obispo County Air Pollution Control District, April 2012, Page iv)* (https://www.prcity.com/DocumentCenter/View/14604/CEQA-Air-Quality-Handbook---2012-Volume-1-PDF) states:

  "Sensitive Receptors: Sensitive receptors are people that have an increased sensitivity to air pollution or environmental contaminants. **Sensitive receptor locations** include schools, **parks** and playgrounds, day care centers, nursing homes, hospitals, and residential dwelling unit(s). **The location of sensitive receptors is needed to assess toxic impacts on public health**."
  *Hidden Falls Regional Park Trail Expansion Subsequent DEIR, Chapter 9, Air Quality (2020)* states:

  "Recreational land uses are considered moderately sensitive to air pollution. Exercise places a high demand on respiratory functions, which can be impaired by air pollution, even though exposure periods during exercise are generally short. In addition, noticeable air pollution can detract from the enjoyment of recreation."

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

CSP agrees with Placer County's analysis about recognizing the importance of insuring protection for recreational trail users and park employees from air quality impacts. Empire Mine State Historic Park's boundary is 450 away from the Project's Brunswick facility's boundary, with many popular trails within 1000 feet.

- *Health Risk Assessment*
  - On *Page 4.3-61*: "The TAC emissions associated with blasting and crushing, ore processing, and earthwork and material handling would include asbestos and silica emitted from the fugitive dust produced."
    - CSP appreciates knowing this information as this is of utmost concern for the health of the Park. Silica is mentioned 10 times within the DEIR, with many references to negative health consequences when inhaled. CSP can find no mention of threshold values for silica inhalation or estimated emissions within the DEIR. In *Appendix E.1 Air Quality and Greenhouse Gas Emissions Analysis Technical Report for the Idaho-Maryland Mine Project Nevada County, California*, silica emissions were found on *page 25* in *Table 10. Project Annual On-Site Operational TAC Emissions* which listed silica emissions of 4.32-4.42 tons per year for the operational phases of *Year 2022 to 2026 – Mining, Brunswick Industrial Site Operations, Fill Placement at Centennial Industrial Site* and *Year 2027 to 2032 – Mining, Brunswick Industrial Site Operations, Fill Placement at Brunswick Industrial Site*. Considering the amount of silica potentially emitted from the Project there is no reference of the threshold values that the California Office of Environmental Health Hazard Assessment (OEHHA) have established in the Adoption of Chronic Reference Exposure Levels for Silica (Crystalline, Respirable) *Feb 10, 2005*. CSP requests a transparent evaluation of how 4.32-4.42 tons per year of silica emissions from operational phases of the Project would correspond to the Inhalation Reference Exposure Level of 3 µg/m3 that OEHHA have established in the Adopted Chronic Reference Exposure Levels for Silica (Crystalline, Respirable), and in particular reference to the Park's users and employees as a *sensitive receptor*. Without this information CSP has found it impossible to evaluate this potential health impact.

**Agcy 1-7**

  - On *Page 4.3-62*: "Blasting and crushing would also result in emissions of heavy metal TACs including arsenic, beryllium, cadmium, copper, lead, manganese, mercury, nickel, selenium, and vanadium."
    - CSP appreciates knowing this information as this is of utmost concern for the health of the Park, employees, residents, and its visitors. CSP can find no relevant information on exact threshold values for each of the above state heavy metals and has found it impossible therefore to evaluate this potential impact to the Park's

**Agcy 1-8**

  - On *Page 4.3-62*: "However, it should be noted that mine operations would be required to comply with MSHA PELs that protect underground workers from asbestos fiber. The protections sufficient to meet the MSHA PELs would result in

**Agcy 1-9**

7

limiting the potential emissions of asbestos aboveground from the shaft in general."

- CSP believes this statement relies on a false pretense that following Mine Safety and Health Administration permissible exposure limits (PEL) for asbestos for individual mine workers during a shift will also "limit" asbestos emissions aboveground "in general." How are the PELs being achieved for mine workers and how does this relate to limiting asbestos being released into the aboveground environment? Asbestos pollution is of extreme concern for CSP, and we would like clarification on the above assumption.

Agcy 1-10

- On *Page 4.3-62*: "A dispersion modeling analysis was conducted for the HRA of DPM emitted from diesel vehicles and off-road equipment, blasting emissions, and TACs from fugitive dust sources on the project sites. A full list of emission sources and the parameters used to model each source may be found in the HRA included within Appendix E.1 to this EIR."
  - CSP has reviewed Appendix E.1 and the Health Risk Assessment included within and cannot find a discussion, map or table disclosing the locations(s) of where the actual dispersion of air pollutants would be transported to and from the Project sites, besides a "Wind Rose" graph from the Blue Canyon meteorological station. CSP requests a detailed map displaying modelled air pollutant levels at nearby "Sensitive Receptors" and for the region in general. CSP cannot effectively interpret the air quality impact data as is currently presented to evaluate risks for Empire Mine SHP resources, personnel, and recreational users.

Agcy 1-11

- On *Page 4.3-62*: "Discrete cartesian receptors were placed at residents proximate to the project sites. A uniform Cartesian grid of 4,426 by 3,299 meters was centered over the project sites to capture the maximum point of impact and extent of the plume isopleth."
  - CSP cannot find a detailed discussion, map, or table of this "grid". CSP requests to know where the "maximum point of impact and extent of the plume isopleth" is located. CSP cannot effectively evaluate impacts to the Park, employees, residents, and recreational users without knowing this important crucial data.

Agcy 1-12

- *On Page 4.3-65: Applicant Proposed Emissions Reduction Measures*
  - APM-AQ-2: Surface Fugitive Dust Controls
    - "The following measures shall be implemented to reduce surface fugitive dust emissions: During construction, operation, and reclamation, all exposed soil surfaces (e.g., unpaved disturbed areas, unpaved parking areas, and unpaved staging areas, and soil piles) shall be adequately wetted to ensure that no visible dust crosses the property boundary, except when rains are occurring. As an alternative to watering, inactive soil piles shall be covered to minimize wind erosion. During construction, all on-site roadways shall be paved as soon as possible after grading and

any unpaved gravel roads shall be treated with chemical stabilizers in order to control fugitive dust."

- CSP has found no details on what the "chemical stabilizers" are within the DEIR. There are exactly four mentions of the chemical stabilizers within the entire DEIR, and no analysis of potential hazards associated with their potential release into the environment. CSP believes all "chemicals" associated with the project should be disclosed and evaluated for potential impacts, especially if they could be water soluble and find an entryway to South Fork Wolf Creek from surface runoff or become airborne.

- *Project-Specific Impacts and Mitigation Measures - 4.3-1 Conflict with or obstruct implementation of the applicable air quality plan. Based on the analysis below and with implementation of mitigation, the impact is less than significant.*

  - *Page 4.3-70*: "Therefore, prior to mitigation, the project would result in potentially significant levels of ROG, NOx, and PM10 emissions and could conflict with or obstruct implementation of the Ozone Attainment Plan pursuant to Criterion 1."
    - CSP recognizes this potential for air quality impacts and is very concerned about this issue in regard to the health and welfare of the Park, its employees, residents, and visitors. CSP is in full support of the Ozone Attainment Plan to insure the region's future health.

**Agcy 1-13**

  - *Page 4.3-73*: "Conclusion - Based on the analysis presented above, the proposed project would comply with Criterion 2. However, as presented in Table 4.3-17, emissions of ROG, NOx, and PM10 would be potentially significant (Level A or B) during construction, operations, and reclamation, and mitigation would be required in order for the project to comply with Criterion 1. Because the project would not comply with Criterion 1 without mitigation, implementation of the project could conflict with the Ozone Attainment Plan, and implementation of the project could create a conflict with or obstruct implementation of the applicable air quality plan related to the region's nonattainment status for ozone and PM10, resulting in a significant impact prior to implementation of mitigation."
    - CSP recognizes this potential for air quality impacts and is very concerned about ozone and PM10 pollution in regard to the health and welfare of the Park. CSP is in full support of the Ozone Attainment Plan to insure the region's future health.

  - *Page 4.3-73*: "Mitigation Measure(s) The emission data presented in Table 4.3-17 (i.e., unmitigated emissions) reflect the reductions that would occur with implementation of APM-AQ-1 and APM-AQ-2. Table 4.3-19 shows the estimated maximum daily mitigated emissions associated with construction, operation, and reclamation of the project, accounting for additional emissions reductions associated with Mitigation Measure 4.3-1(b), which would result in a reduction in construction contractors' equipment exhaust criteria air pollutants during project construction (year 2021)."

**Agcy 1-14**

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

- Mitigation Measure 4.3-1(b) *Construction Exhaust Emissions Minimization Plan* is wholly based on the exact duplication of *Applicant Proposed Emissions Reduction Measure APM-AQ-1 Exhaust Emission Controls (page 4.3-65)*. CSP believes that this mitigation must be in error and questions how can the exact duplicate mitigation achieve a reduction in air quality emissions, when "unmitigated emissions" already reflected a reduction in emissions with using *California Air Resources Board (CARB) certified Tier 4 Final engines* with the applicant's own APM-AQ-1 *Exhaust Emission Controls* mitigation? According to the CEQA process, mitigations should be clear in the process of how they will effectively mitigate the impact [*Sundstrom* v. *County of Mendocino* (1988) 202 Cal.App.3d 296]. Since this mitigation is unclear at best how it would achieve any reductions in air quality impacts, CSP believes that Mitigation Measure 4.3-1(b) should be null and void and would thus change the impact to *Significant.*

**Agcy 1-15**

- CSP believes Project Impact 4.3-1 is still *significant* even after all stated mitigations (even with questioning the duplicate mitigations detailed above), based on Northern Sierra Air Quality Management District (NSAQMD) criteria. CSP believes the project would still conflict with the Ozone Attainment Plan based on NSAQMD criteria even after "implementation of mitigation", by measurements of the applicant's own air quality impact data. The differences in emissions from *Table 4.3-17 Maximum Unmitigated Daily Project Emissions (lbs/day)* to *Table 4.3-19 Maximum Mitigated Daily Project Emissions (lbs/day)* are almost negligible for NOx and PM10, and in some cases have no reduction in emissions at all. NOx unmitigated emissions during *Year 2022 to 2026 – Mining, Brunswick Industrial Site Operations, Fill Placement at Centennial Industrial Site* is listed at 107.49 lbs/day and after mitigation measures is still listed at 107.49 lbs/day, which still qualifies as significant under NSAQMD criteria. PM10 is listed at 54.40 lbs/day for "Unmitigated" and the exact same 54.40 lbs/day for "Mitigated". NOx and PM10 Values for *Year 2027 to 2032 – Mining, Brunswick Industrial Site Operations, Fill Placement at Brunswick Industrial Site* and *Year 2033 to 2102 – Mining, Brunswick Industrial Site Operations, Fill Placement at Off-Site Location* are also the exact same for both figures. Mitigation for NOx and PM10 has not been achieved by any actual reduction in values.

**Agcy 1-16**

*Page 4.3-73*: "Additional reductions could not be quantified for Mitigation Measure 4.3-1(a), which are the NSAQMD recommended mitigation measures that are applicable to the project. According to the NSAQMD, implementation of recommended mitigation measures for Level A and B thresholds (included as Mitigation Measure 4.3-1[b] below) would reduce project impacts to a less-than-significant level during all years of project construction, operations, and reclamation."

10

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

- CSP believes the reference to *Mitigation Measure 4.3-1[b]* is in error. The components in *Mitigation 4.3-1[b]* are not listed anywhere within any NSAQMD relevant documents. NSAQMD's recommended mitigations are instead correctly listed as *Mitigation 4.3-1(a)* on *Table 2-1 Summary of Impacts and Mitigation Measures* and on *Page 4.3-77* and can be correctly identified in Guidelines For Assessing And Mitigating Air Quality Impacts Of Land Use Projects, Section I. Mitigations for Use During Design and Construction Phases" (NSAQMD, revised 2009).

**Agcy 1-17**

- Although the Project would put forth mitigations listed under the NSAQMD's "Guidelines" in *Mitigation 4.3-1(a)* the project is noted to still have air pollutant threshold "Level B" of $NO_x$ *after* mitigations for the following project phases: *Year 2022 to 2026 – Mining, Brunswick Industrial Site Operations, Fill Placement at Centennial Industrial Site Year 2027 to 2032 – Mining, Brunswick Industrial Site Operations, Fill Placement at Brunswick Industrial Site and Year 2033 to 2102 – Mining, Brunswick Industrial Site Operations, Fill Placement at Off-Site Location*. The NSAQMD "Guidelines For Assessing And Mitigating Air Quality Impacts Of Land Use Projects" document clearly states in Step Three: Emission Thresholds of Significance, Page 9 that "*NOx, ROG and PM10 emissions must be mitigated to a level below significant. If emissions for NOx, ROG and PM10 exceeds 136 pounds per day (Level C), then there is a significant impact; below Level C is potentially significant.*" CSP therefore believes emissions are clearly still *potentially significant* even after mitigations.

**Agcy 1-18**

- *Chapter 4.3 – Air Quality, Greenhouse Gas Emissions, and Energy* and *Appendix E.1 Air Quality and Greenhouse Gas Emissions Analysis Technical Report for the Idaho-Maryland Mine Project Nevada County, California* fails to mention that the NSAQMD also requires that projects follow the mitigations in the "IV. Mitigation for Land Use Emissions" section of the "Guidelines," as this is foremost a "Land Use" project. Unfortunately, regardless of this omission, the applicable mitigations under section IV. from the NSAQMD appear to be based on a "Land Use" residential housing / retail shopping development with the following mitigations listed:
  - *IV. Mitigation for Land Use Emissions for Classification as Level B or Level C Threshold*
    - *a. The project shall incorporate mixed uses, where permitted by local development regulations, to achieve a balance of commercial, employment, retail and housing options where feasible.*
    - *b. Larger projects shall provide for neighborhood parks or other recreational options such as trails to minimize vehicle travel to off-site recreational uses and/or commercial areas.*

11

- *c. The project should provide densities of nine units per acre or greater, where allowed by the General Plan and/or Zone Plan, along bus routes and at bus stops to encourage transit use, where feasible.*

CSP understands then that these mitigations are clearly not applicable to a Land Use project centered on mining extraction and have no use in this Project for significantly reducing air quality impacts. Fortunately, the NSAQMD does allow for the Lead Agency in CEQA projects to "revise" mitigations and admits that the list of mitigations within the "Guidelines" are not "*all-inclusive*" and are only a "*suggested list*" on Page 10. The "Guidelines" state that "*the District will request that the lead agency review a suggested list of mitigations (below) for both short-term and long-term sources. This list is not all-inclusive, and may be revised by the lead agency. During the CEQA review process, the District recommend (or the applicant may propose) additional, project-specific mitigation measures.*"

Since both *Mitigation Measure 4.3-1(a)* and *4.3-1(b)* have been clearly shown to be inadequate in mitigating air quality impacts, and without other applicable mitigation written guidance from the NSAQMD, CSP requests that Nevada County follow NSAQMD's suggestion to revise the mitigation measures for Air Quality impacts to include more *project-specific mitigations*.

- *Project-Specific Impacts and Mitigation Measures - 4.3-2 Expose sensitive receptors to substantial pollutant concentrations. Based on the analysis below and with implementation of mitigation, the impact is less than significant.*

Agcy 1-19

As discussed on Page 3 and Pages 5-7 of these comments, CSP has detailed how Empire Mine State Historic Park has been neglected to be evaluated as a *sensitive receptor*. With the Park located 450 feet away from the Brunswick facility boundary and 900 feet south of the Centennial facility, CSP believes that air pollutants of concern from the project would impact Park recreational users and Park employees. CSP cannot effectively evaluate if the Park would be *exposed to substantial pollutant concentrations* of both toxic air contaminants (TACs) and *Criteria Pollutants* NOx and PM10 without a thorough discussion, visual representation, and analysis centered on the Park as a sensitive receptor. CSP therefore requests that *Impact 4.3-2* be changed to *potentially significant* until the DEIR can be shown to prove mitigations would be effective at reducing the impacts to *less than significant* for the Park.

Agcy 1-20

- CSP further believes its concerns about the potential for both TAC's and NOx and PM10 impacting the health of the Park and its users is the DEIR's reliance on inadequate mitigations from Impact 4.3-1 that were detailed on pages 8-11 of these comments. The DEIR makes the following statements on *Page 4.3-81*:

- "Because ROG and NOx emissions associated with project construction, operation, and reclamation would be potentially significant before mitigation, the project could minimally contribute to regional O3 concentrations and the associated health effects."

- "Health effects that result from NOx (including NO2) include respiratory irritation. NOx emissions from project construction, operation, and reclamation would occur at NSAQMD threshold Level B."

- "Construction, operation, and reclamation of the project would result in PM10 emissions at NSAQMD threshold Level A, which would be considered potentially significant before mitigation. As such, the project would potentially contribute to exceedances of the CAAQS for PM10, and would potentially obstruct the MCAB from coming into attainment for this pollutant. The project would be required to comply with NSAQMD Rule 207, Particulate Matter, and would implement APM-AQ-2, Surface Fugitive Dust Controls, which would limit the amount of dust generated during project implementation. By reducing the generation of fugitive dust through compliance with the foregoing NSAQMD rules and APM-AQ-2, emissions of PM10 would be reduced to the maximum extent practicable and receptors would not be exposed to excess pollutant concentrations."

With the DEIR's own admissions above that O3 and NOx emissions can lead to negative health impacts, there is no verifiable data within this section to refute that "receptors would not be exposed to excess pollutant concentrations." NOx emissions are stated to be exactly the same in the Project for all phases after construction even after mitigation, which is *Potentially Significant* according to NSAQMD. Mitigation measure APM-AQ-2 has already been factored in *Table 4.3-17 Maximum Unmitigated Daily Project Emissions (lbs/day)* and has also been found to stay at the same levels for all phases of the Project post construction.

***Chapter 4.3 – Chapter 4.4 – Biological Resources***

- *4.4-2 Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status wildlife species in local or regional plans, policies, or regulations, or by the CDFW or USFWS. Based on the analysis below and with implementation of mitigation, the impact is less than significant.*

**Agcy 1-21**

  - CSP believes that the impact should be changed to *potentially significant* based on the potential that either Foothill Yellow Legged Frog, California Red-Legged Frog, or Willow Flycatcher may occupy downstream habitat within the South Fork Wolf Creek riparian corridor on Empire Mine State Historic Park lands. Downstream habitat at the Park has not been adequately evaluated by the Project's biological consultants. CSP believes that the Project's mine de-watering, subsequent non seasonal

flooding, and contribution to erratic and fluctuating water levels within South Fork Wolf Creek could disrupt potential sensitive or special status wildlife species within the Park.

- CSP has detected an occurrence of *Empidonax traillii*, Willow Flycatcher, (CA state listed "Endangered") within the Bennett Street Grasslands adjacent to the South Fork Wolf Creek in the recent past. CSP believes that the cumulative potential impact of mine dewatering on the riparian corridor, coupled with potential noise and vibration impacts, warrants review for sensitive or special status wildlife in downstream and nearby lands including at the Park.

**Agcy 1-22**

- *Foothill Yellow Legged Frog - Chapter 4.4 – Biological Resources*
  - *Page 4.4-69* states: "Given the species has not been previously identified within the South Fork Wolf Creek watershed and only marginal suitable habitat occurs within the Brunswick Industrial Site for the species, there is a very low likelihood this species occurs within the South Fork Wolf Creek."
    - CSP disagrees with the assumptions made above that there is a "very low likelihood this species occurs within the South Fork Wolf Creek." Documentation and evaluation of downstream habitat within the South Fork Wolf Creek riparian has been wholly inadequate within the DEIR and is based on one occurrence within the *Reconnaissance Level Biological Resources Field Surveys* section on *Page 4.4-53* when contract biologist Greg Matuzak surveyed an unknown section of South Fork Wolf Creek on Park property on August 29, 2019.

**Agcy 1-23**

  - *Page 4.4-70* states: "Therefore, based on the conclusion of Balance, potential downstream impacts to the stream channel and associated riparian zone along both sides of South Fork Wolf Creek from the additional discharge of 5.6 cfs would be minimal on sensitive biological resources, such as foothill yellow-legged frog, and do not represent a potential significant impact to the stream channel or associated riparian zone within South Fork Wolf Creek."
    - CSP disagrees that additional discharge of 5.6 cfs would be minimal on sensitive biological resources. The DEIR does not contain adequate analysis concerning the nature of the Project's mine de-watering proposal, specifically relating to erratic and fluctuating water inputs that have been detailed on *Page 70, 4.0 Project Effects* in *Appendix K.2 Groundwater Hydrology And Water Quality Analysis Report For The Idaho-Maryland Mine Project -Nevada County, California* and in *Chapter 4.8 – Hydrology and Water Quality Page 4.8-45*:
      - "Initial dewatering of the Idaho-Maryland Mine will occur at a rate of 2,500 gpm, or 5.6 cfs. If this rate of dewatering is achieved it would take approximately 160 days (5.3 months) to dewater the underground

**Agcy 1-24**

workings, assuming an average groundwater inflow rate into the existing mine workings of 850 gpm and total water currently in the mine workings of 385 million gallons. After that time, the dewatering will continue at a rate equal to the groundwater inflow into the mine, ranging from approximately 500 gpm to 1200 gpm seasonally and averaging approximately 850 gpm or about 1.9 cfs. The maximum discharge rate permitted will be 2,500 gpm, which will allow flexibility for unexpected seasonal inflows, operational issues, and increased groundwater inflows from the expansion of the mine during operations."

- CSP is extremely concerned with this project detail that would allow maintenance dewatering to occur up to 5.6 cfs at any time during the life of the Project. Water levels within South Fork Wolf Creek could theoretically change above baseline conditions from less than 1.9 cfs to 5.6 cfs depending on mine operations. Fluctuating water levels especially during the summer months when creeks normally return to a slower flow could have potential to disrupt many forms of life dependent on the normal ebbs and flows of riparian water levels. CSP has no mechanism to evaluate the impacts from erratic and fluctuating water levels during the summer breeding months, and unfortunately the DEIR does not attempt too either.

**Agcy 1-25**

- Considering the above-mentioned project proposal and comments, CSP is especially concerned with how proposed fluctuating water levels within South Fork Wolf Creek would impact potentially occurring species such as the Foothill Yellow Legged Frog. "California Herps" website states that Foothill Yellow Legged Frogs "mating and egg-laying occurs exclusively in streams and rivers (not in ponds or lakes) from April until early July, after streams have slowed from winter runoff." Amphibians in general rely on a slow, steady water level to insure egg survival.

**Agcy 1-26**

- *Non-Special Status Birds Protected by Other Laws, Wildlife Disturbance*
  - *Page 4.4-74* states: "Above-ground activities would generate noise during project operations, including placement of engineered fill, shaft ventilation fan, exterior pumps outside the process plant building, water treatment plant pumps and turbine aerator, and Brunswick shaft skipping within the headframe building. However, it is important to remember that most protected species have a low to very low potential to occur on the Centennial Industrial Site and Brunswick Area."
    - CSP requests an evaluation of generated noise impacts on wildlife within the nearby areas of the Park, including the northwest corner of the Union Hill area (450 feet away from Brunswick facility boundary), and the Bennett Street Grasslands (900 feet away from the Centennial site). CSP cannot adequately

evaluate potential noise impacts on sensitive potential wildlife species including detected "California Birds of Special Concern" Yellow Warbler, Yellow Breasted Chat, and Olive-sided Flycatcher from the information within the DEIR.

- *Mitigation Measures*
  - *Foothill Yellow-Legged Frog, 4.4-2(a) Pre-construction Survey and Avoidance and Minimization Measures. Page 4.4-75*
  - *California Red-Legged Frog 4.4-2(c) Pre-construction Survey and Avoidance and Minimization Measures. Page 4.4-77*

**Agcy 1-27**

- Both the above mitigations require preconstruction surveys on the Project sites within riparian and wetland habitats. Since the DEIR has not adequately evaluated downstream potential for either species of frogs to occur, these mitigations would not adequately protect either species if found within the riparian corridor of South Fork Wolf Creek or within known wetland habitat at the Bennett Street Grasslands that are both held within the Park. CSP has established previously in these comments that fluctuating and erratic water levels from mine dewatering maintenance proposed actions (referenced from *Page 70, 4.0 Project Effects* in *Appendix K.2* and *Chapter 4.8 – Hydrology and Water Quality Page 4.8-45)* could have unknown and potentially negative impacts to amphibian habitat, especially regarding breeding. CSP requests both an evaluation of the South Fork Wolf Creek riparian and wetland habitats within the Park, for both Foothill Yellow Legged and California Red Legged Frogs to be included in the DEIR, and for the Park lands along the South Fork Wolf Creek to be included in *Pre-construction Survey and Avoidance and Minimization Measures 4.4-2(a)* and *(c)*.

- *4.4-3 Have a substantial adverse effect on riparian habitat or other sensitive natural community, or State or Federally protected wetlands (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means. Based on the analysis below and with implementation of mitigation, the impact is less than significant*

**Agcy 1-28**

  - *Page 4.4-87* states: "Conclusion - Based on the above, implementation of the proposed project at the Centennial Industrial Site and Brunswick Industrial Site, and East Bennett ROWs could have a substantial adverse effect on riparian habitat and/or other sensitive natural communities and/or have a substantial adverse effect on State or Federally protected aquatic resources (including, but not limited to, marsh, vernal pool, coastal, etc.), through direct removal, filling, hydrological interruption, or other means. Thus, a *significant* impact could occur."
    - "Mitigation Measure(s) Implementation of the following mitigation measures would reduce the above impact to a level."
      - Although CSP appreciates the mitigations listed to protect the immediate riparian and wetland habitats within the Brunswick and Centennial

properties, CSP disagrees that the Mitigation Measures listed under impact 4.4-3 would reduce the impact of substantial adverse effects on riparian habitats and/or sensitive natural communities to *less-than-significant*. Mitigation measures fail to address and thus adequately protect downstream riparian habitat and sensitive natural communities from "hydrological interruption or other means" due to proposed mine dewatering inputs into the South Fork Wolf Creek which could fluctuate from 1.9-5.6 cfs for the life of the Project (referenced from *Page 70, 4.0 Project Effects* in *Appendix K.2)*.

- CSP has the following California Department of Fish and Wildlife Sensitive Natural Communities known within the Park adjacent to the South Fork Wolf Creek riparian area at either the Bennett Street Grasslands or the "Upstream Reach" (Sensitive Natural Communities from been identified from the California Sensitive Natural Communities list updated August 18, 2021):
  - 41.050.05 *Danthonia californica*
  - 61.201.01 *Salix lasiolepis*
  - 61.420.07 *Alnus rhombifolia / Cornus sericea*
  - 52.206.01 *Grindelia camporum*
  - 45.165.01 *Carex densa*
  - 82.200.50 *Pseudotsuga menziesii – Arbutus menziesii*
  - 61.450.01 *Acer macrophyllum / Rubus ursinus*

- CSP cannot adequately evaluate potential effects to existing "Sensitive Natural Communities," riparian trees, willow thickets, amphibian and fish spawning habitat, and benthic macroinvertebrates held within the Park from the information given within the DEIR.

***Chapter 4.7 – Hazards and Hazardous Materials***

*Project-Specific Impacts and Mitigation Measures*

- *4.7-1 Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials. Based on the analysis below, with implementation of mitigation, the impact related to transportation, storage and use of hazardous materials is considered less than significant.*

**Agcy 1-29**

- CSP is validly concerned with the manner in which explosives and their constituent components will be handled, particularly during transport, delivery and unloading at the Brunswick site. CSP appreciates that several relevant regulations are cited (49 CFR 177 subpart B, 49 CFR 397.7), but the specific process by which explosives will be received, documented, and transferred to storage in the "Service Shaft" is not described in the DEIR. In addition, the added potential hazards for local Nevada County Roadways with transporting explosives routinely and the potential for accidents are of concern for CSP. For this reason, we cannot adequately understand the risks, nor could

the applicant mitigate for the potentially significant impacts, of such explosives, particularly as a potential hazard source of wildfire ignition. CSP also believes that the quantity and frequency of explosives deliveries have not been evaluated. CSP believes that based on the potential for an accident based on the sheer volume of explosives used and transported in the Project, this impact should be changed to *potentially significant*.

***Chapter 4.8 – Hydrology and Water Quality***

- *Regional Hydrology*
  - *Page 4.8-4* states: "Peak flow rates for a 10-year, 24-hour storm event and a 100-year, 24-hour storm event have been reported by Cranmer Engineering, Inc. (Cranmer, 1986) as part of the development of the Storm Drainage Master Plan for the City of Grass Valley. For **South Fork Wolf Creek** at Hennessy School (i.e., the 2.75 square mile area of the watershed upstream of State Route [SR] 49), **Cranmer (1986) calculated peak flow rates of 658 cfs for the 10-year, 24-hour storm, and 1,087 cfs for the 100-year, 24-hour storm**. Thus, peak flow rates during significant storm events may be as much as two-to-three orders of magnitude (100 times to 1,000 times) greater than the base flow in, or the NID discharges to, South Fork Wolf Creek.

Agcy 1-30

    - With respect to Cranmer (1986), CSP disputes the stated calculated peak flow rates for the South Fork Wolf Creek that are referenced above and believes they could misinform the public and agencies regarding the hydrological system inherent to this watershed. The original document referenced within *Appendix K.2* "Cranmer Engineering, Inc. (1986). *City of Grass Valley, Storm Drainage Master Plan and Criteria*. Priority List Summary, page 2." (https://www.cityofgrassvalley.com/sites/main/files/file-attachments/sd_master_plan_priority_list.pdf?1617826732) is only a table of storm drainage features with no documentation on how values were calculated. The estimate for 658 cfs for a 10-year, 24-hour storm is located at an open concrete ditch adjacent to the Hennessey School which Cranmer notes that it needs a 98 inch (8 feet) diameter concrete pipe, which is approximately the width of the existing channel in 2022. CSP does not have figures for baseline or peak flow measurements at this site, but for comparison, the South Yuba River located in Nevada County, considered the largest river in Nevada County, has an average baseline flow of 150-600 cfs during the winter months peaking in the 1000's during storm events at the Jones Bar USGS gauge station (https://www.dreamflows.com/graphs/avg.065.php). CSP has measured flows at the Bennett Street Grasslands portion of the South Fork Wolf Creek as high as 11 cfs within the past two winters. CSP staff theorize winter storms can average as high as 20 cfs potentially, but disagree with figures in the hundreds or thousands, regardless of the magnitude of the storm.

  - *Page 4.8-4* states: "Based on the stream gaging data and manual measurements made in 2019 to January 2021, base flows range from 0.07 cfs in the summer to 6.5

Agcy 1-31

cfs in the winter. Peak flow during the monitoring period occurred on April 5, 2020 at 33.4 cfs in response to a two-day rainfall event totaling approximately 10 inches."

- CSP appreciates knowing flow measurements for the South Fork Wolf Creek upstream from its properties, and notes that according to the data in *Appendix I – Record of South Fork Wolf Creek Streamflow* contained within *Appendix K.2*, the average "Daily Mean Streamflow" during fall/winter 2020 was as low as 0.2 cfs, with Daily Mean Streamflows as high as 4 cfs during storm events. For reference CSP has measured flows manually as high as 11 cfs within the last two years on the South Fork Wolf Creek. Recently on 03/16/2022 flow was recorded as only .69 cfs by Park staff, and routinely have been measured from 1-2 cfs after average storm events. Winter storm events have been captured from 4-11 cfs on Park property. CSP staff theorize peak flows as high as 20 cfs are common every few years on the South Fork Wolf Creek.

Agcy 1-32

- *South Fork Wolf Creek Geomorphology, Page 4.8-26* states: "South Fork Wolf Creek - Reach D - Reach D receives runoff and sediment from a watershed of approximately 2.2 square miles (U.S. Geological Survey [USGS], 2019). The average reach slope was measured to be 0.5 percent. The reach is in an unconfined valley with an active floodplain and riparian zone and exhibits poolriffle morphology, defined by an undulating bed with a sequence of sediment bars, pools, and riffles. Bars and riffles are comprised of mostly gravel-sized sediment."
  - CSP would like to acknowledge that "Reach D" is contained entirely within the Park at the Bennett Street Grasslands and its ecosystem health is of utmost importance to CSP.
  - *Figure 4.8-9, South Fork Wolf Creek Reaches in Project Vicinity* on *Page 4.8-25* incorrectly displays Empire Mine State Historic Park borders and does not include the Bennett Street Grasslands, which are featured as the entirety of "Reach D."

Agcy 1-33

- *4.8.3 Regulatory Context - Federal Clean Water Act*
  - CSP appreciates an overview of the regulatory framework from the Clean Water Act on *Pages 4.8-26-27*, but missing from this subsection is an excerpt from *Appendix K.1 Geomorphic Assessment SF Wolf Creek, page 5:* "2.1 The Clean Water Act - The United States Environmental Protection Agency (USEPA), through the state regulatory agency (Central Valley Regional Water Quality Control Board, or RWQCB), issues general permits for industrial discharges under the National Pollutant Discharge Elimination System (NPDES). Under the NPDES, a Limited Threat Discharge permit may be authorized for discharges that are relatively pollutant-free and present no or minimal threat to water quality or the environment, **including harm or impairment to existing beneficial uses of receiving waters** (RWQCB, 2018)."

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

- CSP would like to acknowledge the repeated theme present in many local, state and federal regulations about protecting downstream ("receiving waters") beneficial uses.

- *4.8.3 Regulatory Context - Central Valley Regional Water Quality Control Board*

  - CSP appreciates including the following excerpt on *Page 4.8-28* which includes reference to protecting "beneficial uses" such as "aquatic resources" from water quality degradation, which would include the whole of South Fork Wolf Creek on Park lands:

    - "As authorized by the Porter-Cologne Water Quality Control Act, the CVRWQCB primary function is to protect the quality of the waters within its jurisdiction for all beneficial uses. State law defines beneficial uses of California's waters that may be protected against quality degradation to include, but not be limited to: domestic; municipal; agricultural and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and **preservation and enhancement of fish, wildlife, and other aquatic resources or preserves**."

**Agcy 1-34**

- *4.8.3 Regulatory Context – Basin Plans*

  - As CSP detailed in the "General Comments" above on Pages 2-3, the concept of "Beneficial Uses" is of critical importance to an evaluation of potential impacts to the downstream portions of South Fork Wolf Creek below the Brunswick facility. CSP appreciates the overview of the CVRWQCB 2018 Sacramento and San Juaquin Basin Plan on *Page 4.8-31* that references the protection of "Beneficial Uses" eight times, including "non-contact water recreation, including aesthetic enjoyment; warm and cold freshwater habitat; and wildlife habitat. These uses describe current "use" of the South Fork Wolf Creek within Park lands.

**Agcy 1-35**

- *Local Regulations - Nevada County General Plan - Page 4.8-33*

  - CSP appreciates the review of *Policy FH-10.3.2, Safety Element - Goal FH-10.3 Reduce the potential for injury, property damage, and environmental damage from flooding* which states "**Avoid increases in downstream flooding potential by protecting natural drainage**". CSP acknowledges that the Project's proposal to release up to 5.6 cfs of mine water into South Fork Wolf Creek conflicts with this policy.

**Agcy 1-36**

  - CSP appreciates the review of *Policy 11.6A, Water Element - Goal 11.1 Identify, protect and manage for sustainable water resources and riparian habitats* which states: "New development shall minimize the discharge of pollutants into surface water drainages by providing the following improvements or similar methods which provide equal or greater runoff control: (a) include curbs and gutters on arterials, collectors, and local roads consistent with adopted urban street designs; and (b) **oil, grease, and silt traps** for subdivisions creating five or more parcels and commercial and industrial development of one acre or greater size. Maintenance of such facilities shall be assured through a

**Agcy 1-37**

20

legally enforceable mechanism." CSP has found no mention of "oil, grease and silt traps" within the Project's proposal in the DEIR. Protecting the South Fork Wolf Creek from oil and sediment runoff from the Brunswick facility is of utmost importance to CSP. CSP requests to evaluate a detailed Industrial Stormwater Pollution Prevention Plan (I-SWPPP) as part of this DEIR. CSP cannot evaluate impacts to the South Fork Wolf Creek from potential degradation to water quality from surface runoff pollutants without a I-SWPPP addressing these concerns.

Agcy 1-38

- CSP appreciates the review of *Policy 17.11(c), Mineral Management – Goal 17.1* "Requiring that any increase or decrease of off-site discharge is not detrimental to the downstream environment or downstream water users." CSP acknowledges that the Project's plan for mine dewatering potentially conflicts with this regulation. CSP cannot evaluate potential impacts to the South Fork Wolf Creek from erratic and fluctuating water levels from the information contained within the DEIR at present.

- *4.8.4 Impacts And Mitigation Measures*

  - *4.8-2 Substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the project may impede sustainable groundwater management of the basin. Based on the analysis below, with the implementation of mitigation the impact is less than significant.*

    - CSP finds this Impact and the discussion that follows confusing and misleading. The first section states on *Page 4.8-54*: "Thus, the project could not impede sustainable groundwater management within a groundwater basin, because no such basin exists in the project vicinity", while then discussing groundwater depletion effects to residential wells, and thusly requiring mitigations.

Agcy 1-39

- CSP requests a complete and separate *Impact* based on groundwater depletion and evaluation of effects to the surrounding region, including not only residential wells, but also on the surrounding ecosystem. CSP owns property within Empire Mine SHP that will be affected by groundwater depletion (according to *Figure 4.8-12 Well Locations and Itasca Drawdown* on *Page 4.8-63*). Properties include mature coniferous forests at Union Hill, riparian forests of the "Upstream Reach" and of Bennett Street Grasslands along the South Fork Wolf Creek, and wet meadows within Bennett Street Grasslands.

- CSP cannot evaluate impacts from groundwater depletion of 1-5 feet within the Park since no such model exists within the DEIR. Potential effects of a lessening water table could be tree mortality and die-off of existing plant communities. CSP recognizes these are unknowns, but again needs a mechanism for evaluation.

- CSP cannot effectively evaluate impacts of groundwater depletion modeling on the Park, as the boundaries of Empire Mine SHP are

not present on either *Figure 4.8-12 Well Locations and Itasca Drawdown*, *Figure 4.8-11 Simulated Drawdown of Groundwater Levels at End of Future Mining Relative to 2019 Water Level*, or on *Figure 4.8-13 Potential Expansion of Future Mine*, nor were any maps or figures included in *Appendix K.2 Groundwater Hydrology and Water Quality Analysis* displaying Park boundaries. CSP requests all relevant maps and figures of groundwater depletion to include the boundaries of Empire Mine State Historic Park and only then can CSP staff effectively evaluate this impact.

- *Mitigation Measure 4.8-2(a)*:
  - *Page 4.8-67*: "The project applicant shall implement the Groundwater Monitoring Plan (GMP) prepared by Itasca Denver, Inc. (February 2021), as approved by the County."

Agcy 1-40

    - While CSP appreciates the proposal for Groundwater Monitoring before mine dewatering commences, we respectfully request Groundwater Monitoring to also include portions of the Park, located within the "Upstream Reach" and within the Bennett Street Grasslands in areas that are modeled to have groundwater depletion on *Figure 4.8-12 Well Locations and Itasca Drawdown*.

- *Mitigation Measure 4.8-2(b)* and *(c)*:
  - CSP recognizes that *Mitigation Measure 4.8-2 (b)* and *(c)* are wholly focused on supplying lost groundwater to residential well customers.

Agcy 1-41

  - CSP recognizes that the Project is focusing on mitigating the impact of groundwater depletion through *Mitigation Measures 4.8-2 (a-c)*. CSP requests a complete analysis of groundwater depletion within the affected portions of the Park. Once analysis is complete, an appropriate mitigation should be created for any potential effects on vegetation communities within the Park.

- *Impact 4.8-3*, *Page* "Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner which would:

Agcy 1-42

  *i) Result in substantial erosion or siltation on- or off-site?*
  *ii) Substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site?*
  *iii) Create or contribute to runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?*

*iv) Impede or redirect flood flows?*

Based on the analysis below and with implementation of mitigation, the impact is *less than significant*."

- CSP acknowledges that this impact *may* be "*less than significant*" for the South Fork Wolf Creek based on hydrological technical reports *Appendix K.1 and K.2* detailing that "substantial" erosion or siltation would not occur at 5.6 cfs of mine dewatering. However, even Balance Hydrologics found in *Appendix K.1* in *Figure 5-6 Preliminary suspended-sediment load rating curve, South Fork Wolf Creek above proposed discharge location, Nevada County, California* that between 0.6-0.7 tons of day of sediment transport happen at flows of 5-6 cfs. CSP staff has noted visible Turbidity at flows equal and greater than 4 cfs.

  In addition, although 5.6 cfs of flow within the South Fork Wolf Creek may not contribute to "substantial erosion," adding an additional 5.6 cfs to winter storm event flows with a baseline flow over 15 cfs would, according to *Page 4.8-74:*

  - "Sediment pebble count analysis conducted by Balance (2020) indicates that the flow rate at which sediment within the channel may become mobilized ranges from 20 cfs to 90 cfs."

  Balance Hydrologics and EMKO Environmental, Inc. theorize that the threshold for "bedload sediment mobility" is 23 cfs in the following statement on *Page 4.8-74:*

  - "With the addition of the maximum proposed discharge of 5.6 cfs and increasing measured baseflows by a 50 percent safety factor, post-project baseflows during nonstorm periods would be expected to range between approximately 5.8 cfs and 15 cfs. These estimates are less than 23 cfs, the threshold for bedload sediment mobility and well below flows that commonly exhibit significant work on the channel (i.e., 1- to 2-year flood). Balance therefore concludes that discharges during baseflow periods would not result in substantial erosion or siltation on site in South Fork Wolf Creek. ECM is in agreement with Balance that the addition of 5.6 cfs to the South Fork of Wolf Creek drainage basin would have no significant effect on the stream channel or banks, or to the turbidity of the South Fork Wolf Creek."

    - CSP disputes the notion that 23 cfs is a *definite* threshold for bedload sediment mobility. The figure of 23 cfs is referenced from *Appendix K.1* on *Page 27:* "Using indirect methods to estimate peak in Reach D3, peak flow from the December event was estimated to be approximately 23 cfs." CSP cannot base evaluation of sediment mobility based on one *indirect* measurement within one year of monitoring. Balance did note that sediment was not substantially mobile at flows below 17.3 cfs, in *Appendix K.1* on *Page 39:* "Field measurements at stream flows between 11 cfs and 17.3 cfs showed no active bedload transport". CSP does not dispute

the observation and appreciates this information that substantial erosion was not evident at flows less than 17.3 cfs. CSP thus can effectively agree that it appears that bedload sediment mobility happens above 17.3 cfs, but potentially not lower based on Balance Hydrologics' assessments.

**Agcy 1-43**

- CSP also disputes the notion that "that the addition of 5.6 cfs to the South Fork of Wolf Creek drainage basin would have no significant effect on the stream channel or banks, or to the turbidity of the South Fork Wolf Creek." CSP believes this statement assumes that there is not a potential baseline flow of ~12 cfs existent post winter storm, whereby flows would then combine to +17.6 cfs and thereby *potentially* contribute to bedload sediment mobility.

**Agcy 1-44**

- CSP also disputes that 5.6 cfs would not have a "significant effect" on "turbidity of the South Fork Wolf Creek". Balance Hydrologics have established in *Appendix K.1* in *Figure 5-6 Preliminary suspended-sediment load rating curve, South Fork Wolf Creek above proposed discharge location, Nevada County, California* that between 0.6-0.7 tons a day of sediment transport happen at flows of 5-6 cfs. Balance has also noted "slightly turbid" water present on 1/24/2020 at a flow of 1.56 cfs; "very turbid" water on 1/26/20 at a flow of 11 cfs; "water slightly turbid" on 3/18/2020 at a flow of 3.22 cfs; "slightly turbid" on 3/29/20 at a flow of 1.91 cfs; "upper watershed channel is very turbid" on 4/5/20 at a flow of 20.4 *cfs*; "Slightly turbid" on 4/7/20 at a flow of 4.14. cfs; (figures taken from *Appendix I – Record of South Fork Wolf Creek Streamflow* contained within *Appendix K.2*).

**Agcy 1-45**

Based on Balance Hydrologics' own observations that turbidity exists in some form above or equal to 1.56 cfs, with "very turbid" water existing above or equal to 11 cfs, and the DEIR stating on *Page 4.8-74*: "post-project baseflows during nonstorm periods would be expected to range between approximately 5.8 cfs and 15 cfs," CSP believes that turbidity in the South Fork Wolf Creek would be *potentially* significant. "Very turbid" water would potentially occur from 11 -15 cfs during "post-project baseflow". *Appendix K.1* in *Figure 5-6 Preliminary suspended-sediment load rating curve, South Fork Wolf Creek above proposed discharge location, Nevada County, California* displays approximately between 0.6-0.7 tons of day of sediment transport happen at flows of 5-6 cfs, and at 10 cfs this figure is approximately 1.2 tons per day. The DEIR does not adequately relay how many tons of sediment transport is acceptable without mitigations, or before this impact is considered *significant*. CSP therefore requests that *Impact 4.8.3* should be changed to *potentially significant* regarding turbidity (suspended sediments) and acknowledges that the addition of 5.6 cfs of mine dewatering also would bring the South Fork closer to its erosion potential during storm events, (within 2.3 cfs) of *potential* substantial erosion and siltation "off-site" within the Park.

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

***Chapter 4.9 – Land Use and Population and Housing***

- *Impact 4.9-2 Cause a significant environmental impact due to a conflict with any land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect. Based on the analysis below, the impact is less than significant.*

  - CSP disagrees with the analysis of *impact 4.9-2*, and requests that this impact be changed to *potentially significant* based on the following conflicts with regional, local and statewide land use plans, policies and regulations:

    - Nevada County General Plan, Volume 1 Goals, Objectives, Policies, & Implementation Measures
      - *Safety Element - Goal FH-10.3 Reduce the potential for injury, property damage, and environmental damage from flooding.*
        - *Policy FH-10.3.2*
          - ***Avoid increases in downstream flooding potential by protecting natural drainage** and vegetative patterns through project site plan review, application of Comprehensive Site Development Standards, use of clustered development and project subdivision design. The Comprehensive Site Development Standards shall include measures applicable to all discretionary and ministerial projects to **avoid downstream flooding resulting from new development.** Such measures, shall include, but not be limited to:*
            *a. Avoidance of stream channel modifications; and*
            *b. Avoidance of excessive areas of impervious surfaces; and c. Use of on-site retention or detention of stormwater.*
      - *Water Element - Goal 11.1 Identify, **protect and manage for sustainable water resources and riparian habitats**.*
      - *Mineral Management - Goal 17.1 Recognize and protect valuable mineral resources for current and future generations in a manner that **does not create land use conflicts**.*
        - *Policy 17.11*
          - *Recognize the importance of water conservation and quality for the present and future needs of the County by: a. Requiring the conservation of on-site water during mining operations; b. Requiring that off-site water discharge complies with State water quality standards; and **c. Requiring that any increase or decrease of off-site discharge is not detrimental to the downstream environment or downstream water users**.*

    - CA Water Code § 13050 section (f) states: "'**Beneficial uses**' of the waters of the state that may be protected against quality degradation include preservation and enhancement of fish, wildlife, and other aquatic resources or preserves.
      - (d) "**Waste**" includes sewage and any and all other waste substances, **liquid**, solid, gaseous, or radioactive, associated with human habitation, or

**Agcy 1-46**

25

of human or animal origin, or **from any producing, manufacturing, or processing operation**, including waste placed within containers of whatever nature prior to, and for purposes of, disposal.

- (1) **Beneficial uses to be protected.**
- (l) (1) **"Pollution" means an alteration of the quality of the waters of the state by waste to a degree which unreasonably affects either of the following: (A) The waters for beneficial uses."**

The Central Valley Regional Water Quality Control Board established in their 2018, Sacramento and San Juaquin Basin Plan that "**Fish, plants, and other wildlife, as well as humans, use water beneficially"** (Page 2-1, Beneficial Uses, California Regional Water Quality Control Board, Central Valley Region, (RWQCB), 2018), and that existing "Beneficial Uses" of the Bear River Watershed which includes South Fork Wolf Creek are "Wildlife Habitat" and "Cold and Warm Freshwater Habitat" (page 2-10, RWQCB).

These land use policies conflict with the Project's proposal to discharge mine water into the South Fork Wolf Creek and contribute to increased turbidity / sedimentation. The Project's mine dewatering plan would also significantly alter the downstream immediate riparian ecosystem with unknown consequences for amphibians, riparian trees, benthic macroinvertebrates and sensitive vegetation communities, especially considering the proposal to alter flows up to 5.6 cfs at any time within the next 80 years.

***Chapter 4.10 – Noise and Vibration***

- *Existing Sensitive Receptors, Page 4.10-4*

Agcy 1-47

CSP pointed out in our "General Comments" that the Park has been neglected to be included as a "sensitive receptor" in evaluation and analysis of Noise and Vibration impacts on the recreational users, park employees/residents, and wildlife resources within the nearest locations to both the Brunswick and Centennial facilities. CSP has noted though that Sensitive Receptor #8 on *Figure 4.10-2 Representative Sensitive Receptors* is located at the eastern border of the Bennett Street Grasslands and just outside the Park. CSP has little ability to evaluate and analyze potential noise and vibration impacts along the Union Hill trails within the Park, with the nearest Sensitive Receptor #30 located several hundred feet away, albeit closer in location to the Brunswick facility. The "Upstream Reach" of Park land located on East Bennett Road is nearby to Sensitive Receptor #9. Sensitive Receptor #9 has been identified as having a ***Daytime Noise Criteria Exceeded*** in *Table 4.10-11 Predicted Construction Noise Levels at Nearest Receptors*. Wildlife existent at the "Upstream Reach" will therefore be impacted by excessive noise and CSP is concerned about how this impact will affect wildlife health.

- *Impact 4.10-1 Generation of a substantial temporary increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies, due to initial construction activities. Based on the analysis below, even with the implementation of mitigation, the impact would be considered significant and unavoidable.*

**Agcy 1-48**

  - CSP notes that this *significant and unavoidable* impact would affect Park lands in the "Upstream Reach" area adjacent to East Bennett Street nearby to Sensitive Receptor #9 which is unfortunate and may impact wildlife resources health, breeding, and foraging habits. Black bear, deer, amphibians, reptiles, and numerous avian species, which may include sensitive species are known from this area of the Park.

***Chapter 4.13 – Wildfire***

As owner, operator and manager of Empire Mine State Historic Park, wildfire potential within the region and nearby to the Park is of the utmost concern to CSP. Protecting natural and cultural resources, park recreational visitors, park employees/residents, and park infrastructure from the effects of wildfire, the health effects of wildfire smoke, is of the greatest interest to CSP. Although not fully evaluated within *Chapter 4.13* the Project proposed to install two 12,000 gallon diesel tanks, and use numerous flammable chemicals and explosives daily during both construction and operational phases. These Project constituents are inherently hazardous and can exacerbate wildfire potential if improperly handled and / or released. CSP recognizes that most of these issues were analyzed and evaluated within *Chapter 4.7 Hazards and Hazardous Materials*, but the relation to wildfire danger and potential is inherent to this chapter.

**Agcy 1-49**

*Fuel Treatment Efforts*

  - CSP notes that *Figure 4.13-2 Active, Completed, and Planned Fuel Treatment Projects* is missing fuel treatments that have occurred in the Union Hill area of Empire Mine State Historic Park from 2014-2021. This area of Union Hill is directly west uphill of the Brunswick facility and is located 450 feet away from the Brunswick boundary.

- *Impact 4.13-2 Due to slope, prevailing winds, and other factors, exacerbate wildfire risks, and thereby expose project occupants to, pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire. Based on the analysis below, and with implementation of mitigation, the impact is less than significant.*

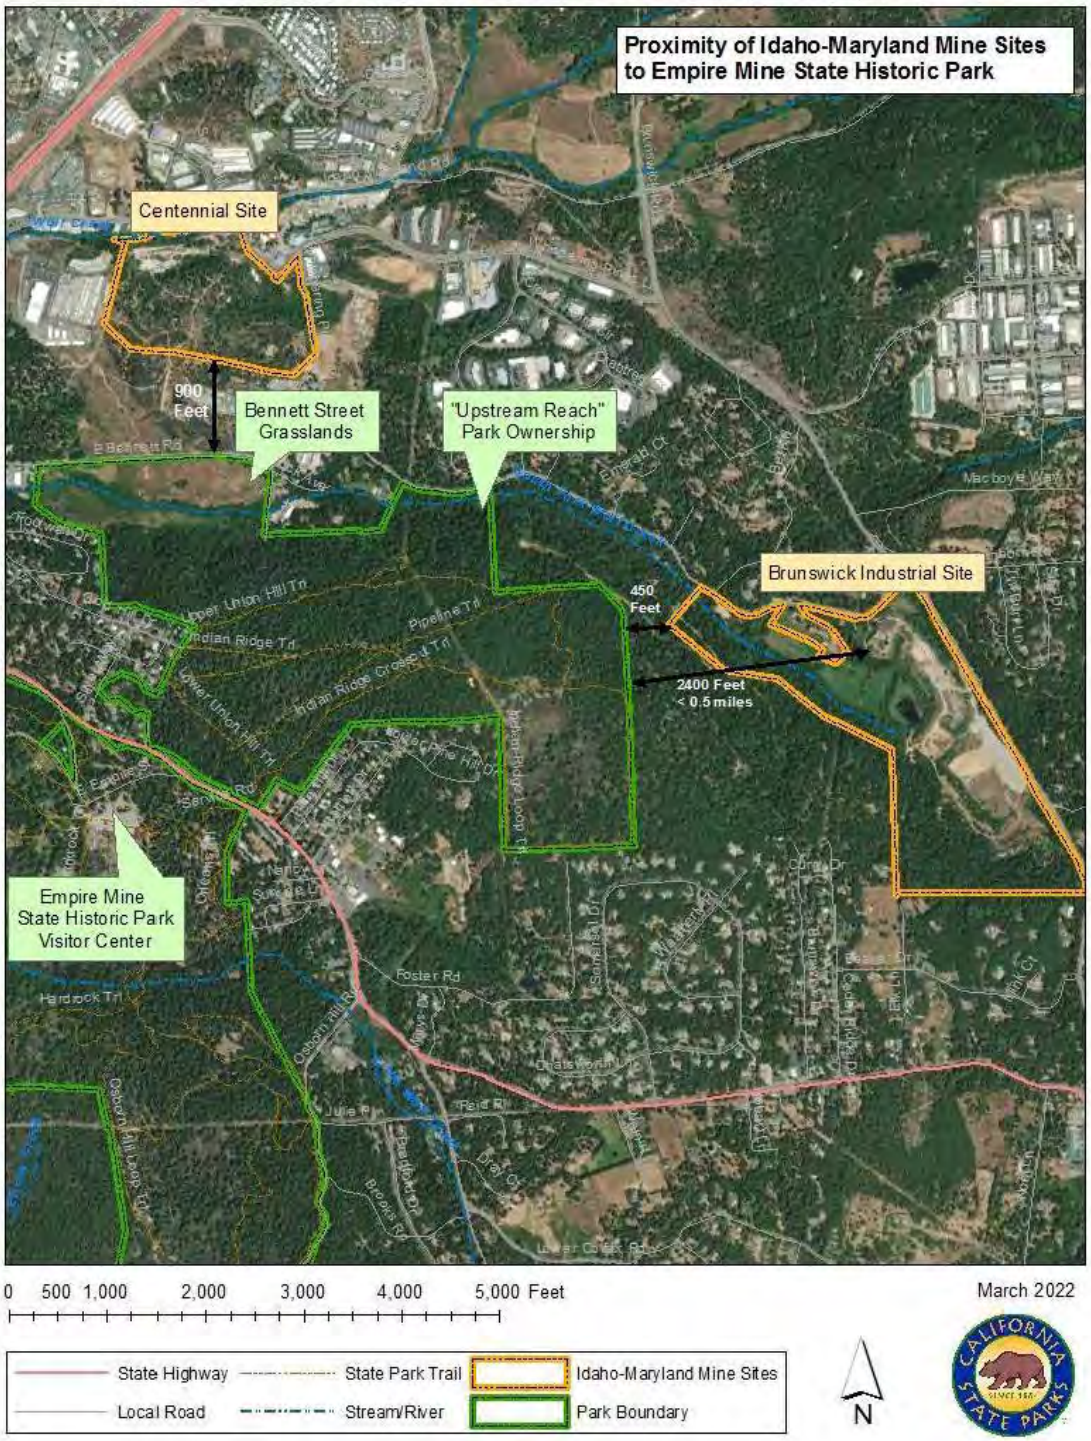
**Agcy 1-50**

  - CSP notes both erroneous and speculative information on groundwater depletion in relation to plant community health and uptake of water in the discussion following: *Impact 4.13-2. Page 4.13-21* states: "In the areas away from the creeks and valleys, the depth to groundwater is typically greater than 10 feet and, in many cases, may be 100 feet or more. In addition, the normal seasonal fluctuation in the depth to groundwater may be 10 feet to 30 feet or more. Thus, in the areas away from the creeks, the existing groundwater surface is below the typical depth of rooted vegetation

and tap roots from trees, especially during the drier months when the depth to groundwater is at its greatest."

- CSP has noted that this information contradicts *Footnote 8* in *Appendix K.2*: "The most common tree in the project area is the Ponderosa Pine, with tap roots up to 36 feet deep, which is considered one of the deepest tap root systems among conifer trees. The second most common tree in the project area is the Incense Cedar, with tap roots up to 20 feet deep but averaging six to seven feet deep. Other trees in the area include the Douglas Fir, with tap roots up to 10 feet deep, and the California Black Oak, with tap roots three to four feet deep (Greg Matuzak, personal communication, October 24, 2020 electronic mail message to Ben Mossman, Rise Gold)."
    - CSP notes that ponderosa pine and incense cedar are the two most common tree species at the Park and are located in abundance throughout Union Hill area, which is nearest to the greatest groundwater potential drawdown areas. If these tree species are known to have tap roots from 20-36 feet deep, then these tree roots have great potential to be within the groundwater zone of "typically greater than 10 feet and, in many cases, may be 100 feet or more" even while being located "away from the creeks and valleys". CSP also notes that there is no reference or scale given to support the theory that groundwater is "typically greater than 10 feet and, in many cases, may be 100 feet or more" in areas away from valley and creek bottoms. CSP cannot evaluate impacts to vegetation based on speculation without reference.

Agcy 1-51



- CSP also notes the following paragraph on *Page 4.13-21* states: "Discharge of treated water to South Fork Wolf Creek would prevent the lowering of the groundwater levels along the reach of that creek because the full dewatering volume would be discharged to the creek, whereas only a small fraction of the groundwater that was removed from the subsurface would come from that area. Thus, the potential increased recharge due to the enhanced base flow in South Fork Wolf Creek would more than offset any effects from dewatering in the area near the creek."
    - CSP finds that this information supports the notion that only the immediate riparian area along South Fork Wolf Creek would receive groundwater recharge from extra mine dewatering. CSP believes this still leaves vegetation communities within the valley bottom, but away from the creek especially vulnerable to artificial groundwater depletion. Many of these vegetation communities exist at the Bennett Street Grasslands within the Park and may be potentially affected by groundwater depletion however minimal it may be. Vegetation communities drying out sooner not only threatens their long-term survival during the summer drought but can contribute to lower humidity levels within the plants and therefore higher flammability and ignition potential.

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

**Agcy 1-52**

CSP also notes that the information on groundwater depletion in relation to the health of plant communities and tree survival was left out of *Chapter 4.8 Hydrology and Water Quality*. CSP noted within the comments to *Chapter 4.8* that evaluating impacts to vegetation communities due to groundwater depletion was of high concern for the Park in relation to "*Impact 4.8-2 Substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the project may impede sustainable groundwater management of the basin. Based on the analysis below, with the implementation of mitigation the impact is less than significant.*"

California Department of Parks and Recreation comments on the Draft Environmental Impact Report
State Clearinghouse #2020070378 for the proposed Idaho-Maryland Mine Project

## AGENCY LETTER 1: DANIEL LUBIN, CALIFORNIA DEPARTMENT OF PARKS AND RECREATION

### Response to Comment Agcy 1-1

The commenter provides a description and information regarding the Empire Mine State Historic Park. Comment noted.

The commenter requested it be noted that an undisturbed historic "sulphurette works" is located on the "upstream Reach" of the Park, located 0.4-mile downstream of the Brunswick site on South Fork Wolf Creek but does not provide any information as to why this is relevant to the analysis of the DEIR. The comment is noted.

### Response to Comment Agcy 1-2

The commenter states that the DEIR is inadequate in mitigations and several sections are unclear as to what the potential impacts may be. The commenter states that the project could affect the natural resources, recreational values, health and safety of Park visitors and employees and the general well-being of the Park, but does not provide specific examples in this comment. Responses to specific comments are provided below.

### Response to Comment Agcy 1-3

The commenter believes that the project and the impacts and mitigations in the DEIR fail to adequately protect the South Fork of Wolf Creek, its riparian ecosystem, and its "Beneficial Uses". Specifically, the commenter asserts that the proposal to add 1.5 to 5.6 cfs to South Fork Wolf Creek threatens the riparian ecosystem, plant communities, benthic macroinvertebrates, may cause erosion and degradation of bank stability, discharge heavy metals, cause turbidity, and harm aquatic habitat and amphibians. The commenter asserts that the project conflicts with Policy 17.11 of the Nevada County General Plan due to increase in offsite water discharge to South Fork Wolf Creek which could be extremely detrimental to the downstream environment and water users of which include wildlife and riparian streams. Please see Master Responses 32 - Temperature of Mine Water Discharge, 33 - Groundwater Dependent Vegetation, 34 - Resident Fish, 35 - Discharge to South Fork Wolf Creek, 36 - Flows in South Fork Wolf Creek, 38 -Foothill Yellow Legged Frog and California Red Legged Frog, and Response to Comment Grp 31-12 regarding benthic macroinvertebrates.

### Response to Comment Agcy 1-4

The commenter states that the Park users have been neglected to be considered a sensitive receptor regarding air quality. Please see Response to Comment Agcy 1-6.

The commenter states that the Park users have been neglected to be considered a sensitive receptor regarding noise. Please see Response to Comment Agcy 1-47 and Agcy 1-48.

### Response to Comment Agcy 1-5

The commenter states that the CSP owns a large section of the free-flowing stretch of South Fork Wolf Creek downstream of the project. Comment noted.

The commenter requests extensive revisions to the DEIR to add discussions of the Empire State Historic Park. A revision to page 4.3-11 has been made to the DEIR (see Response to Comment Agcy 1-6) as reflected in the Final EIR. In addition, maps have been prepared that depict cancer and non-cancer health risk isopleths to clarify the location of the park and modeled health risk. Please see Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K. The park boundaries have been added to Sheet 16 which is attached to the Final EIR as Appendix L.

The Bennett Street Grasslands are discussed in Master Response 33 - Groundwater Dependent Vegetation. No other revisions regarding the Empire State Historic Park are required for the analysis of the DEIR.

## Response to Comment Agcy 1-6

The commenter asserts that the air quality analysis used in the DEIR did not include parks and playgrounds in the definition of sensitive receptors and may have omitted analysis of recreational trail users on Empire Mine State Historic Park's trail system as sensitive receptors. Recreational parks have been added to the definition of Sensitive Receptors in Chapter 4.3 (Air Quality, Greenhouse Gas Emissions, and Energy) on page 4.3-11:

> Some land uses are considered more sensitive to air pollution than others due to the types of population groups or activities involved. Children, pregnant women, older adults, and people with existing health problems are especially vulnerable to the effects of air pollution. Accordingly, land uses where sensitive-receptor population groups are likely to be located such as hospitals, schools, childcare centers, residences, and retirement homes, are considered especially vulnerable. Recreational parks and uses are also areas that may have sensitive receptor visitors.

This definition would include the Empire Mine State Historic Park. Notably, however, based on proximity to the project, predominant wind direction, and duration of exposure, the maximally exposed individual described in the Health Risk Assessment (HRA), located north of the project site at UTM coordinates 671091 meter Easting /4342277 meters Northing (see page 27 of HRA included in Appendix E.1 of the DEIR) would not change.

## Response to Comment Agcy 1-7

The commenter asserts that the DEIR did not properly assess silica exposure to sensitive receptors based on the threshold values established by OEHHA, and should evaluate silica exposure from the project to Empire Mine Park users and employees. OEHHA has established a chronic (i.e., long-term) reference exposure level (REL) for Crystalline silica (quartz, cristobalite, tridymite) of respirable size (defined as 4 micrometer particle aerodynamic diameter). According to OEHHA's *Air Toxics Hot Spots Program Risk Assessment Guidelines – Guidance Manual for Preparation of Health Risk Assessments* (2015) (OEHHA's Guidelines):

> A REL is the concentration level at or below which no adverse non-cancer health effects are anticipated for the specified exposure duration. RELs are based on the most sensitive, relevant, adverse health effect reported in the medical and toxicological literature. RELs are designed to protect the most sensitive individuals in the population by the inclusion of factors that account for uncertainties as well as individual differences in human susceptibility to chemical exposures. The factors used in the calculation of RELs are meant to err on the side of public health protection in order to avoid underestimation of non-cancer hazards. Exceeding the REL does not automatically indicate an adverse health impact. However, increasing concentrations above the REL value increases the likelihood that the health effect will occur.

As discussed on page 4.3-79 and shown in Table 4.3-21 of the DEIR, the threshold of significance for chronic exposure is a Hazard Quotient of 1. The Chronic Hazard Quotient is equal to the annual average concentration at the receptor location divided by the Chronic REL. To determine if TACs exceed the Chronic Hazard Quotient, the annual mass emissions (in tons per year) of each applicable TAC, including silica, were converted to substance-specific emission rates (in grams/second) and then to annual average concentrations by multiplying the substance-specific emission rate by the "Chi over Q" ("X/Q") value estimated by the AERMOD dispersion model. As described in the Health Risk Assessment prepared for the project (Appendix E.1 of the EIR), "A

unit emission rate (1 gram per second [g/s]) was normalized over each unique source of emissions for the AERMOD run to obtain the "X/Q" values. X/Q is a dispersion factor that is the average effluent concentration normalized by source strength, and is used as a way to simplify the representation of emissions from many sources." Based on these calculations, the Health Risk Assessment prepared for the project determined that the health risk to the maximally exposed sensitive receptor would be below the Hazard Quotient threshold and would result in a less than significant impact. In addition, maps have been prepared that depict cancer and non-cancer health risk isopleths to clarify the location of the park and modeled health risk, as further described below.

Several commenters requested visual representations of the results of the Health Risk Assessment (HRA) prepared for the project and attached to the DEIR as Appendix E.1. Based on public comments asking for visual exhibits and for more detail on exposure to workers, Dudek prepared a supplemental HRA ("Dudek Memo") to assess potential for impacts to workers near the project sites, and also to include visual representations of the residential receptors identified in the original HRA used in the DEIR's analysis. Please see Appendix K to this Final EIR for the Dudek Memo.

The Dudek Memo identifies the worker receptors shown on Exhibits A through D based on the supplemental HRA, but also includes the residential receptors, based on data from the original HRA used in the DEIR. There are no residential receptors in the proximity of the Centennial Industrial Site, so no residential receptors are indicated on the exhibits. The locations of residential and worker receptors are annotated on Exhibits A through D of the memo. In the case of the calculated worker health risk, no isopleths are shown at the Centennial Industrial Site because there is no location on-site or off-site where health risk exceeds a level of significance. The health risk to the maximally exposed individual worker (MEIW) is calculated in the memo. The MEIW is shown on Exhibit D and is located north of the Centennial Industrial Site. As described in the memo, all project emissions, including trucks, off-road equipment, underground/blasting/crushing, ore processing, fuel tank storage, backup diesel generators, and material handling, were incorporated into the worker HRA.

As shown in Table 1 of the Dudek Memo, the unmitigated and mitigated incremental cancer risk at the MEIW of 0.4 in 1 million (assuming exposure starts at age 16) from project construction and operation would not exceed the NSAQMD threshold of 10 in 1 million. The unmitigated and mitigated chronic hazard index would be 0.4 and 0.4 at the MEIW, respectively, which would be below the NSAQMD threshold of 1.0. The unmitigated and mitigated acute hazard index would be 0.04 and 0.04 at the MEIW, respectively, which would be below the NSAQMD threshold of 1.0.

## Response to Comment Agcy 1-8

The commenter asserts that it could not find information in the DEIR related to the threshold values for exposure to metal in dust emissions, and therefore cannot assess risks to park employees and visitors. Metal content of dust emissions are considered in the Health Risk Assessment prepared for the project based on sampling and material ratios presented in Section 4.4 of Appendix K.2 to the DEIR. Metals can have cancer and/or non-cancer health risk, and both types of risk were assessed in the DEIR. As described in the Health Risk Assessment for the project:

> In March 2015, the OEHHA approved the 2015 Risk Assessment Guidelines Manual (OEHHA 2015) [termed the "OEHHA Guidelines" in these response to comments]. The construction and operational HRA was prepared following the 2015 Risk Assessment Guidelines Manual. Cancer and noncancer health risk calculations were performed for the project using ground-level unity emission concentration (X/Q) input from AERMOD. This

> modeling established the emissions dispersion field to the existing sensitive receptors from atmospheric influence of the stationary source emissions. Plot files generated in AERMOD were then imported into HARP2, with ground level concentrations determined by multiplication of emission rates and X/Q values for each source of emissions. HARP2 then assessed resulting cancer and noncancer risk at the existing receptors from exposure to TAC emissions using the OEHHA derived calculation method.

This Health Risk Assessment methodology described above is important since the commenter's requested "exact threshold values for each of the above state heavy metals" are automatically incorporated into the California Air Resources Board HARP2 model, which was used to determine the resultant health risk impacts of the project. These values are based on the *Consolidated Table of OEHHA/ARB Approved Risk Assessment Health Values* (last updated in 2020)[1], which the commenter can review if they would like each of the heavy metal health values. Notably, however, the Health Risk Assessment used conservative assumptions of metal content in fugitive dust and concluded that the exposure to the maximally exposed sensitive receptor would be less than relevant thresholds for cancer health risk and chronic health risk. In addition, maps have been prepared that depict cancer and non-cancer health risk isopleths to clarify the location of the park and modeled health risk. The health risk to existing worker receptors was calculated in order to plot the isopleths for the Centennial site, which is surrounded by worker receptors rather than residential receptors. Please see Response to Comment Agcy 1-7 and the Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K. As shown in Exhibits A through D, the isopleths of significant health risk are not within or near the park boundaries and park users would not be subject to significant health risk from the proposed project. Please see Master Response 20 - Conservatism of Metals Assumptions for additional detailed information.

## Response to Comment Agcy 1-9

The commenter cites to language from the DEIR that notes measures to protect underground workers from asbestos exposure under MSHA permissible exposure level (PEL) requirements would also serve to limit emissions of aboveground asbestos exposure, and questions how the PELs will limit aboveground exposure.

While the DEIR correctly points out that measures to reduce airborne asbestos particles in the underground mine will consequently reduce airborne asbestos particles emitted aboveground from the mine, the MSHA PEL is not used by the DEIR as part of the impact analysis to determine the health risk of the public from exposure to airborne asbestos. Rather, the concentrations of asbestos at receptor locations are modelled and the health risk is calculated in accordance with OEHAA guidelines. OEHHA is the lead state agency for the assessment of health risks posed by environmental contaminants in California.

The Health Risk Assessment is based on conservative assumptions. Please see Master Response 22 – Conservatism of Asbestos Assumptions.

The threshold of significance for health risk from exposure to air pollutants including asbestos is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concludes that the health risk to the most sensitive receptor located north of the project site at UTM coordinates 671091 meter Easting /4342277 meters Northing (see page 27 of HRA included in Appendix E.1 of the DEIR), which would receive a greater exposure than visitors or employees at the Empire Mine Park, will be below this threshold.

[1] https://ww2.arb.ca.gov/sites/default/files/classic/toxics/healthval/contable.pdf

## Response to Comment Agcy 1-10

The commenter states that the DEIR does not include an adequate map disclosing the dispersion of air pollutants from the project sites. A map has been prepared to clarify the location of the park and modelled health risk. The health risk to existing worker receptors was calculated in order to plot the isopleths for the Centennial site, which is surrounded by worker receptors rather than residential receptors. Please see Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K. As shown in Exhibits A through D, the isopleths of significant health risk are not within or near the park boundaries and park users would not be subject to significant health risk from the proposed project.

## Response to Comment Agcy 1-11

The commenter states that the DEIR does not include an adequate map disclosing the dispersion of air pollutants from the project sites as relates to the Empire Mine Park. A map has been prepared to clarify the location of the park and modelled health risk. The health risk to existing worker receptors was calculated in order to plot the isopleths for the Centennial site, which is surrounded by worker receptors rather than residential receptors. Please see Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K. As shown in Exhibits A through D, the isopleths of significant health risk are not within or near the park boundaries and park users would not be subject to significant health risk from the proposed project. The threshold of significance for health risk from exposure to air pollutants including asbestos is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concludes that the health risk to the most sensitive receptor located north of the project site at UTM coordinates 671091 meter Easting /4342277 meters Northing (see page 27 of HRA included in Appendix E.1 of the DEIR), which would receive a greater exposure than visitors or employees at the Empire Mine Park, will be below this threshold. The commenter requests a map or grid showing the specific plumes applicable to the park area. This information is not necessary for the DEIR's analysis as it is not directly related to the threshold of significance for the health risk assessment. The maps provided in the Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K, provides sufficient detail to inform the public and the commenter regarding the project's health risk impacts

## Response to Comment Agcy 1-12

The project would use polymers as a chemical stabilizer to reduce haul road dust. These chemicals are not toxic air contaminants and therefore do not require evaluation in the Health Risk Assessment. Research by the US EPA has shown that these types of dust suppressant products have minimal to no adverse impacts on water quality and aquatic life relative to the use of water alone. Please see Master Response 12 – Chemical Dust Stabilizers.

## Response to Comment Agcy 1-13

The commenter expresses support for the Ozone Attainment Plan. As discussed on page 4.3-41 of the DEIR, the NSAQMD established thresholds of significance for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because an AAQS is based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse effects to human health related to criteria pollutant emissions. Notably, the NSAQMD thresholds used for criteria air pollutants for the project are the same thresholds used by the commenter in

the Empire Mine State Historic Park Site Characterization and Remediation Draft Program EIR in 2009.[2]

## Response to Comment Agcy 1-14

The commenter questions how applicant proposed emissions reduction measures can reduce emissions impacts, when those measures were already assumed as part of the "unmitigated emissions" inventory. However, the commenter's question is based on a typo in the DEIR, as the applicant proposed emission reduction measures were not actually included in the unmitigated emissions inventory. Page 4.3-73 of the DEIR had an error, which reads:

"The emission data presented in Table 4.3-17 (i.e., unmitigated emissions) reflect the reductions that would occur with implementation of APM-AQ-1 and APM-AQ-2."

The word "with" was intended to be "without". This error has been corrected in the Final EIR. The unmitigated emissions do not reflect the use of Tier 4F engines; thus, the use of Tier 4F engines does achieve a reduction in emissions as compared to the unmitigated emissions. The typo is hereby corrected on page 4.3-73 of the DEIR:

> Mitigation Measure(s)
>
> The emission data presented in Table 4.3-17 (i.e., unmitigated emissions) reflect the reductions that would occur without implementation of APM-AQ-1 and APM-AQ-2. Table 4.3-19 shows the estimated maximum daily mitigated emissions associated with construction, operation, and reclamation of the project, accounting for additional emissions reductions associated with Mitigation Measure 4.3-1(b), which would result in a reduction in construction contractors' equipment exhaust criteria air pollutants during project construction (year 2021).

The above minor change serves to clarify the DEIR text, and there is no change to the analysis in the DEIR and the impact significance conclusion from the DEIR.

## Response to Comment Agcy 1-15

The commenter asserts that the project should be considered to have a significant and unavoidable impact even after mitigation, regarding Impact 4.3-1. Please see Master Response 19 – NSAQMD Criteria Pollution Thresholds during Operations. As discussed in Master Response 19 - the DEIR imposes all mitigation measures required by the NSAQMD to reduce the project's impacts addressed in Impact 4.3-1 to less than significant.

## Response to Comment Agcy 1-16

The commenter asserts that the DEIR contains a typo, which refers to Mitigation Measure 4.3-1[b] rather than 4.3-1(a). The commenter is correct and page 4.3-73 of the DEIR is hereby revised as follows:

> According to the NSAQMD, implementation of recommended mitigation measures for Level A and B thresholds (included as Mitigation Measure 4.3-1[~~b~~a] below) would reduce project impacts to a *less-than-significant* level during all years of project construction, operations, and reclamation.

The above minor change is for clarification purposes and does not change the analysis or conclusions in the DEIR.

[2] https://www.envirostor.dtsc.ca.gov/public/deliverable_documents/6747547984/Aug%202009%20Empire%20Mine%20Draft%20PEIR.pdf, p. 4.2-20.

## Response to Comment Agcy 1-17

The commenter asserts that the project's ROG, NOx, and $PM_{10}$ emissions should be considered "potentially significant" after mitigation; however, the commenter misunderstands the NSAQMD guidelines. The NSAQMD requires implementation of certain mitigation measures for each defined level of emissions volumes (A, B, C) to achieve an impact determination of less-than-significant impact. As stated on page 4.3-41 of the DEIR, the NSAQMD has developed a tiered approach to significance levels. The tiered thresholds for Levels A, B, and C are given in Table 4.3-5 for a project's estimated emissions of criteria pollutants in pounds per day. A project with emissions qualifying it for Level A thresholds (i.e., all projects with emissions greater than zero) requires the most basic mitigation. Projects that qualify for Level B require more extensive mitigation, and projects that qualify for Level C require the most extensive application of mitigation. If unmitigated emissions of ROG, NOx, and/or PM10 exceed 136 pounds per day (Level C), then there is a potentially significant impact and mitigation is required; if mitigated emissions of ROG, NOx, and/or PM10 still exceed 136 pounds per day (Level C) after implementation of mitigation, then a significant and unavoidable impact would occur. Unmitigated emissions below Level C would result in an impact that is potentially significant, and mitigation is required; following implementation of mitigation (as specified separately for Level A and Level B by NSAQMD), emissions would be less than significant. The DEIR imposes the NSAQMD recommended mitigation measures for the project's ROG, NOx, and $PM_{10}$ emissions, and therefore achieves a less than significant impact, per NSAQMD guidance. (DEIR, p. 4.3-73.) Notably, the NSAQMD thresholds used for criteria air pollutants for the project are the same thresholds used by the commenter in the Empire Mine State Historic Park Site Characterization and Remediation Draft Program EIR in 2009.[3] While the commenter asserts that emissions meeting NSAQMD level B thresholds should be considered "potentially significant" after mitigation, the commenter's 2009 EIR stated that the park project's NOx emissions, which were shown to meet NSAQMD level B thresholds, were "less than significant" after implementation of standard dust control mitigation, similar to the standard mitigation used in the project's DEIR. (See Empire Mine State Historic Park Site Characterization and Remediation Draft Program EIR, pp. 4.2-31 to 4.2-35.) In the Park's EIR, the analysis also relied on the standard NSAQMD mitigation and rules to conclude that emissions impacts would be less than significant, when stating as follows: "To ensure that criteria pollutant emissions are less than significant, the Project Proponents will comply with all applicable NSAQMD and State Rules and Regulations (where applicable) during the execution of Project Actions." (Id. at 4.2-34.) As such, the project's DEIR follows the same methodology for implementation of the NSAQMD's Guidelines For Assessing And Mitigating Air Quality Impacts Of Land Use Projects as was used by the commenter for its own EIR in 2009. Importantly, the DEIR's implementation of the NSAQMD's thresholds is consistent with NSAQMD guidance and implementation of those thresholds by the County on other projects.

## Response to Comment Agcy 1-18

The commenter notes that some of the NSAQMD recommended mitigation measures would not achieve emissions reductions because they are designed for different types of land use projects as compared to an underground mine. The commenter then states that given the mismatch of some of the NSAQMD mitigation measures, the County should require other more project-specific mitigation measures. The DEIR already imposes Mitigation Measure 4-3-1(b), which requires a Construction Exhaust Emissions Minimization Plan that requires the use of Tier 4 Final engines or alternative sources of power. This mitigation measure is, as suggested by the commenter, a

[3] https://www.envirostor.dtsc.ca.gov/public/deliverable_documents/6747547984/Aug%202009%20Empire%20Mine%20Draft%20PEIR.pdf, p. 4.2-20.

measure that is project-specific and beyond the standard measures required by the NSAQMD. The mitigated emissions identified in the DEIR reflect the lower emissions that would be achieved by this mitigation measure. Please see Master Response 19 – NSAQMD Criteria Pollution Thresholds during Operations. Also see Response to Comment Agcy 1-17.

## Response to Comment Agcy 1-19

A map has been prepared to clarify the location of the park and modelled health risk. Please see Dudek Memorandum HRA Isopleths included in the Final EIR as Appendix K. The park boundary is not within, nor close to, the 10 per million cancer risk isopleth which is the boundary for the threshold of significance for health risk. The health risk assessment used in the DEIR already analyzed the health impacts of toxic air contaminant exposure to a maximally exposed individual resident (MEIR) who is much closer to the project site, located north of the project site at UTM coordinates 671091 meter Easting /4342277 meters Northing (see page 27 of HRA included in Appendix E.1 of the DEIR) and would therefore receive higher exposure than the Empire Mine visitors and employees. The air quality analysis prepared for the DEIR found that the MEIR would not be subject to a chronic hazard quotient of 1.0 or greater, and would not be subject to a 10 per million cancer risk, so no significant health impact related to air pollutant exposure is reasonably anticipated at the Empire Mine Park for visitors or employees. Note that the toxic air contaminants contained in particulate matter ($PM_{10}$) emitted by the project's activities are considered in the Health Risk Assessment.

As discussed on page 4.3-2 of the DEIR, pollutants for which ambient air quality standards (AAQS) have been established are called "criteria" pollutants. Criteria pollutants are listed in Table 4.3.1 of the DEIR. NOx and $PM_{10}$ are criteria air pollutants. As discussed on page 4.3-41 of the DEIR, the NSAQMD established thresholds of significance for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because an AAQS is based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse effects to human health related to criteria pollutant emissions. The project complies with the thresholds set by the NSAQMD, applies all required mitigation measures, and therefore would not cause significant health impacts at the Empire Mine Park due to criteria pollutants.

## Response to Comment Agcy 1-20

The commenter expresses concern with health impacts to Empire Mine Park visitors and employees relating to toxic air contaminant and criteria air pollutant emissions from the project, and also asserts that APM-AQ-2 has been factored into the pre-mitigation emissions values in Table 4.3-17 of the DEIR. As discussed in Response to Comment Agcy 1-14 above, the DEIR contains a typo which states that Table 4.3-17 of the DEIR already includes application of APM-AQ-2; however, that table representing unmitigated emissions actually does not include application of APM-AQ-2. That typo has been corrected in the Final EIR.

Further, as discussed on page 4.3-2 of the DEIR, pollutants for which ambient air quality standards (AAQS) have been established are called "criteria" pollutants. Criteria pollutants are listed in Table 4.3.1 of the DEIR. NOx is a criteria air pollutant. As discussed on page 4.3-41 of the DEIR, the NSAQMD established thresholds of significance for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because an AAQS is based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse

effects to human health related to criteria pollutant emissions. Accordingly, these impacts are properly considered less than significant after implementation of mitigation. (DEIR, p. 4.3-73.)

## Response to Comment Agcy 1-21

Please see Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog, and Master Response 37 - Birds and Raptors, regarding potential impacts to these species. In addition, please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts.

## Response to Comment Agcy 1-22

Please see Master Response 37 - Birds and Raptors, regarding potential impacts to the Willow Flycatcher. Please see Master Response 33 - Groundwater Dependent Vegetation, regarding dewatering impacts to riparian zones. Noise and vibration impacts to species was analyzed in DEIR Section 4.4.4, Impact 4.4-2, and considered less than significant.

## Response to Comment Agcy 1-23

Please see Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog. Since publication of the DEIR, a second Foothill Yellow Legged Frog survey was conducted which did not identify any special status amphibian species.

## Response to Comment Agcy 1-24

As discussed on page 4.8-45 of the DEIR, during mining, groundwater inflow into the underground workings would require dewatering. The dewatering would continue at a rate equal to the groundwater inflow into the mine, ranging from approximately 500 gpm to 1,200 gpm seasonally and averaging approximately 850 gpm or about 1.9 cfs. The maximum discharge rate permitted would be 2,500 gpm or 5.6 cfs, which would allow flexibility for unexpected seasonal inflows, operational issues. These fluctuations are substantially less than fluctuations resulting from seasonal storm events and NID discharge (see Appendix K.1 and K.2 of the DEIR). Please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts. Regarding the Foothill Yellow Legged Frog see Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog.

## Response to Comment Agcy 1-25

Please see Response Agcy 1-24 above.

## Response to Comment Agcy 1-26

Noise and vibration impacts to species was analyzed in DEIR Section 4.4.4, Impact 4.4-2, and considered less than significant. The commenter requests a specific noise impact study on wildlife but does not provide any specific reasoning or evidence disputing the conclusions in the DEIR. It should be noted, Brunswick Industrial Site increases in daytime and nighttime ambient noise level increases do not extend to the Empire Mine State Park (EMSP) boundary (see DEIR figure 4.10-7). Engineered fill placement at the Centennial Industrial Site is the closest project activity to the EMSP and could last approximately 6 years. The nearest receptor to the EMSP is number 8 (see DEIR Figure 4.10-3) and the closest noise and vibration measurement location is number 7 and 8 (see Figure 4.10-3). As shown in DEIR Table 4.10-12, Centennial Industrial Site engineered fill activity does not exceed existing baseline noise levels (see Table 4.10-6). As a result, wildlife

species that may use the EMSP should not experience an increase in noise levels and therefore, such impacts would be considered less than significant.

## Response to Comment Agcy 1-27

Please see Response Agcy 1-24 above.

## Response to Comment Agcy 1-28

Please see Response Agcy 1-24 above.

## Response to Comment Agcy 1-29

The commenter states that the specific process by which explosives will be received, documented, and transferred to storage in the surface shaft is not described in the DEIR. However, a robust description of the transfer of explosives underground, and relevant regulations, is provided in Chapter 4.7 of the DEIR. More specific details are not required for the analysis of the DEIR.

The commenter believes that the quantity and frequency of explosives deliveries has not been evaluated in the DEIR and that the impact should be changed to potentially significant. The commenter states that transportation of explosives and potential for accidents, particularly as a potential source of wildfire ignition, and that they cannot understand the risks and the DEIR cannot mitigate the potential significant impact. As stated on page 4.7-24 of the DEIR, during operations, explosives would be transported to the Brunswick Industrial Site a maximum of once a week and a minimum of once every three weeks. During initial underground construction, explosives may be transported to the site more frequently. As stated on page 4.7-25 of the DEIR, the transportation of explosives in the United States has resulted in only a limited number of incidents. A review of DOT incident reports for highway transportation of class 1.1B, 1.4B, 1.1D, and 1.5D materials shows 149 incidents over the past 30 years in the United States. The majority of these incidents were vehicle accidents resulting in no release or spillages. No fatalities were reported in any incidents and only 1 incident resulted in injuries. However, as stated on page 4.7-31 of the DEIR it is already concluded that the proposed project could result in a significant impact related to the routine transport, storage, and use of explosives and mitigation measures are proposed in the DEIR to reduce the impact to a less than significant level.

## Response to Comment Agcy 1-30

The commenter states that it disputes the peak flow rates during storm events which are cited in the DEIR from a 1986 report by Cranmar Engineering. This information was provided by the City of Grass Valley to the applicant during the preparation of the Use Permit application. The calculations used by the City of Grass Valley for their Storm Drainage Master Plan have not been confirmed nor are required to be evaluated in the analysis presented in the DEIR. However, based on other information presented in the DEIR, the Cranmar Engineering report's estimated magnitude of peak flow rates during a 10-year storm is not unreasonable. For example, as shown in Table 4.8-1 of the DEIR, the peak runoff from the Brunswick Industrial Site alone is estimated at 140 cfs during a 10-year storm. This calculation was performed by a registered civil engineer using the unit-hydrograph method consistent with Nevada County standards. The peak storm flow in South Fork Wolf Creek at the location of Empire State Park would be greater due to the larger catchment area at that location. Additionally, Balance Hydrologics, using a regional regression equation, estimated peak flow in South Fork Wolf Creek below Ophir Street (Reach F) at 350 cfs for a 10-year flood. (See page 28 of Appendix K.1). Therefore, peak flows in South Fork Wolf Creek during a 10-year storm event will be much larger than the 20 cfs theorized by the commenter.

## Response to Comment Agcy 1-31

The commenter cites flow volume data observed on the South Fork Wolf Creek and theorizes that peak flows as high as 20 cfs are common every few years. The County concurs that peak storm flows of 20 cfs are expected to occur in South Fork Wolf Creek. A moderate stormflow on January 25-26, 2020, at Reach F was measured at 17.3 cfs in response to 1.25 inches of rainfall. (See page 28 of Appendix K.1). This amount of rainfall is less than a 24-hour one year storm of 3.66 inches, according to the NOAA Atlas Precipitation Frequency Estimate for Grass Valley.

https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html?bkmrk=ca

## Response to Comment Agcy 1-32

The County agrees with the commenter that "Reach D" of South Fork Wolf Creek is within the boundaries of Empire State Park. The commenter correctly states that Figure 4.8-25 of the DEIR does not include a portion of the Empire Mine State Historic Park where the Bennett Street Grasslands are located. However, this figure is reproduced from Figure A-1 of the Geomorphic Assessment (Appendix K.1) and shows a historic overlay prior to the addition of the "Bennett Street Grasslands" to the Park, which explains the discrepancy noted by the commenter. The park boundaries as shown on that map merely reflect the boundaries at the time the historic overlay was created, and do not impact the analysis of the Geomorphic Assessment. Accordingly, the revision of this figure is not necessary.

## Response to Comment Agcy 1-33

The commenter expresses appreciation for a DEIR excerpt explaining the Clean Water Act, and notes that a limited threat discharge permit is appropriate where there will be minimal or no harm or impairment to existing beneficial users or receiving waters. Comment noted.

## Response to Comment Agcy 1-34

The commenter expresses appreciation for a DEIR excerpt regarding protection of aquatic resources from water degradation. Comment noted.

## Response to Comment Agcy 1-35

The commentor expresses appreciation for the overview of the Basin Plan and explanation of beneficial uses provided in the DEIR. Comment noted.

## Response to Comment Agcy 1-36

The commenter asserts that the project would conflict with Nevada General County Plan Policy FH-10.3.2 which states "avoid increases in downstream flooding potential by protecting natural drainage" due to the proposed release of 5.6 cfs of water. However, the project would not increase downstream flooding potential because of the proposed onsite detention pond; therefore, no increase in flooding potential is expected.

As stated on Page 4.8-70 of the DEIR, At the Brunswick Industrial Site, a detention basin would be constructed at the downstream toe of the engineered fill placement slopes, above South Fork Wolf Creek. The detention basin for the Brunswick Industrial Site is sized to detain storm flows to compensate for the quantity of treated mine water discharged to South Fork Wolf Creek, in addition to compensating for increased runoff from potential future industrial development of the site.

During larger storm events, the proposed detention pond on the Brunswick Industrial Site would reduce the peak flows within South Fork Wolf Creek by much more than 5.6 cfs, as shown in Table 4.8-4. Thus, under project conditions, the overall peak storm flows would be lower than they are under existing conditions, resulting in less potential for erosion and sediment transport than

under existing conditions. (See page 75 of the DEIR). As such the project would not conflict with Nevada General County Plan Policy FH-10.3.2.

## Response to Comment Agcy 1-37

The commenter states that the DEIR does not include discussion of oil, grease and silt traps for the Brunswick site in connection with General Plan Policy 11.6A, Water Element – Goal 11.1. As stated on page 4.8-81 of the DEIR, industrial sites are required to have ongoing Industrial permits with the RWQCB that provide permanent water quality protection. Any new projects with Use Permits or Development Permits are required to record a stormwater maintenance covenant on their property prior to operations in conformance with General Plan Policy 3.19C. This provides a legally enforceable mechanism for long-term storm water facility maintenance. If the projects are one-acre or larger, they are also required to provide oil, grease and silt traps on the property pursuant to GP Policy 11.6A. These traps are maintained by the aforementioned storm water facility maintenance covenant.

The commentor states that a detailed Industrial Stormwater Pollution Prevention Plan is required as part of the DEIR. However, the details of this plan are not available because it must be approved by the Central Valley Regional Water Control Board as required in Mitigation Measure 4.8-1(c). The DEIR requires the project site to obtain a SWPPP; however, a SWPPP is submitted after project approval before operations begin, not for review during the CEQA process. Engineering level detail, such as this would be provided in the SWPPP, is not required in an EIR. (*Dry Creek Citizens Coalition v. County of Tulare* (1999) 70 Cal.App.4th 20, 26.)

## Response to Comment Agcy 1-38

The commenter asserts that the project's discharge to South Fork Wolf Creek may be detrimental to the downstream environment or water users. Please see Response to Comment Agcy 1-36. As documented in the DEIR, the peak flood flows within South Fork Wolf Creek under the project would actually be less than current baseline flows due to the detention basin at the Brunswick Industrial Site (see page 4.8-70 of the DEIR). Please see Master Response 36 - Flows in South Fork Wolf Creek, and Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Agcy 1-39

The commenter states that it cannot assess the impact of groundwater depletion within the Empire Mine Park because figures are not included in the DEIR to illustrate the impact. Additionally, the commenter requests a separate impact evaluation for groundwater depletion relating to riparian forests, plant communities and ecosystems. This separate evaluation is not required because groundwater drawdown from mine dewatering would not affect riparian forests or plant communities and ecosystems, including those present inside the Empire Mine Park boundaries. Please see Master Response 33 – Groundwater Dependent Vegetation. Nonetheless, to clarify that groundwater drawdown induced from the mine would not impact groundwater dependant (phreatophytic) vegetation, Itasca Denver prepared a memo showing the simulated drawdown in selected meadows. These three meadows (Brunswick site, Empire Mine Park, and Loma Rica) would experience minimal drawdown, even without consideration of the minewater discharge to South Fork Wolf Creek. The Empire Park Meadow would experience no drawdown with the addition of 1.9 cfs (average maintenance dewatering rate) and less than 1 inch of drawdown with no added flow from mine dewatering. (See Itasca Memo – Simulated Drawdown of Selected Meadows attached to the Final EIR as Appendix H). If the addition of mine water discharge were considered, there would likely be even less impact. As such, these impacts are less than significant.

The park boundaries have been added to Sheet 16, as shown in Appendix L to the Final EIR.

## Response to Comment Agcy 1-40

The commenter proposes additional water level monitoring wells within the Empire Mine Park, the Upstream Reach and within the Bennett Street Grasslands. However, the locations proposed for groundwater monitoring in this comment are in areas where the projected drawdown due to dewatering would be substantially less than normal seasonal fluctuations, and where discharge of treated water would more than offset any potential drawdown due to dewatering. Please see Response to Comment Agcy 1-39 and refer to Sheet 16 attached to the Final EIR as Appendix L. Please also see Itasca Memo – Simulated Drawdown of Selected Meadows, attached to the Final EIR as Appendix H. No significant impact due to dewatering is expected in the Empire Mine Park area, given the existing seasonal fluctuations, low level of drawdown and increased flow in the creek; therefore, monitoring wells within this area is not required.

## Response to Comment Agcy 1-41

An analysis of groundwater drawdown, which includes the area in the boundaries of the park, has already been conducted (see Appendices K.2 and K.3 of the DEIR). Please see Response to Comments Agcy 1-39 and 1-40. Please also see Master Response 33 - Groundwater Dependent Vegetation.

## Response to Comment Agcy 1-42

The commenter disagrees with the DEIR's conclusion that the threshold of bedload sediment mobility is 23 cfs, but seems to agree that bedload sediment mobility in South Fork Wolf Creek is above 17.3 cfs. This comment infers that the project would add 5.6 cfs to winter storm event flows. Please see Response to Comment Agcy 1-36. The detention basin at the Brunswick Industrial Site would reduce peak storm flows in South Fork Wolf Creek by more than 5.6 cfs.

As stated on page 4.8-69 of the DEIR, the analysis is to determine whether the project would result in substantial erosion or siltation. Calculations conducted by Balance indicate that bed sediment becomes mobilized at approximately 20 cfs in reaches of South Fork Wolf Creek that are susceptible to bed mobility. Filed measurements at streamflows up to 17.3 cfs in South Fork Wolf Creek showed no active bedload transport. Balance Hydraulics concluded that the threshold for causation of substantial erosion or sedimentation is greater than 23 cfs. (See page 39 of Appendix K.1.) As the detention basin at the Brunswick Industrial Site would reduce peak storm flows by more than 5.6 cfs, and non-storm flows would remain below even the commenter's suggested lower 17.3 cfs threshold, no significant impacts related to erosion or flooding are expected.

## Response to Comment Agcy 1-43

The threshold for causation of substantial erosion or sedimentation is greater than 23 cfs. Please see Response to Comment Agcy 1-42.

This comment implies that the project would add 5.6 cfs to winter storm event flows. Please see Response to Comment Agcy 1-36. Rather than add to peak flows during storm events, the detention basin at the Brunswick Industrial Site would reduce peak storm flows by more than 5.6 cfs.

## Response to Comment Agcy 1-44

The commenter asserts that the project's proposed discharge of up to 5.6 cfs of water to South Fork Wolf Creek would have a significant effect on turbidity in South Fork Wolf Creek. The commenter cites existing turbidity measured by Balance as evidence that the 5.6 cfs could increase turbidity, but the cited turbidity observations represent baseline conditions and do not point to a potential impact.

Mitigation Measure 4.8-1(a) requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. Water quality standards include total suspended solids and turbidity. Therefore, mine water discharge will not be turbid.

As stated on page 54 of Appendix K.2, turbidity values were also higher in the upstream location, at the proposed treated water discharge point, than they were at the downstream location. This finding suggests that there are existing sources of fine sediment located upstream of the proposed discharge location and additional runoff that enters South Fork Wolf Creek as the flow moves downstream tends to dilute the turbidity from upstream. As shown in Table 3-10 of Appendix K.2, turbidity at Reach B was 79 NTU at 9.7 cfs flow and at Reach F was 48 NTU at 17.3 cfs. As demonstrated by the data, the increase in flow, similar to the maximum proposed discharge, past the proposed discharged point (Reach B) decreased turbidity. As such, the data provided in the DEIR suggests that the maximum 5.6 cfs discharge into South Fork Wolf Creek, which will meet basin plan turbidity standards as required by the RWQCB, will dilute turbidity caused by upstream sources rather than add turbidity to the creek.

## Response to Comment Agcy 1-45

The commenter requests that Impact 4.8.3 be revised to reflect that the project will result in significant turbidity impacts. As stated on page 4.8-69 of the DEIR, the analysis considers whether the project would result in substantial erosion or siltation, not merely the presence of any turbidity. Please see Response to Comment Agcy 1-42. As demonstrated by the data, the increase in flow, similar to the maximum proposed discharge, past the proposed discharged point (Reach B) decreased turbidity due to dilution of turbid water from upstream sources. Please see Response to Comment Agcy 1-44. Additionally, contrary to the commenter's assertion, peak storm flows would be lower than they are under existing conditions due to the construction of a storm water detention pond, resulting in less potential for erosion and sediment transport than under existing conditions during storm events. (See Response to Comment Agcy 1-36).

## Response to Comment Agcy 1-46

The commenter suggests that the DEIR is incorrect in concluding that the project is consistent with the Nevada County General Plan, the California Water Code and the Sacramento and San Joaquin Basin Plan with regard to flooding potential, sustainable water resources and riparian habitats, land use conflicts, detrimental increase in off-site discharge, impacts to beneficial uses due to pollution, and impacts to the ecosystem due to increased turbidity and sedimentation. The commenter generally alleges that the project would conflict with the cited policies and laws, but does not specify how the project would conflict with each policy or law.

With regard to the policies addressing downstream flooding, the project would not increase downstream flooding impacts and would actually reduce peak storm flows due to the construction of a detention pond. Please see Response to Comment Agcy 1-36.

Further, the DEIR has already concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measure 4.8-1(a) to address these potential impacts. This mitigation measure requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. The NOI shall include evaluation of potential constituents of concern and demonstrate that water treatment plant (WTP) design shall successfully treat mine water to meet the water quality standards and treatment goals.

Groundwater drawdown from proposed mine dewatering would not impact groundwater dependent vegetation (riparian trees or sensitive vegetation communities); please see Master Response 33 - Groundwater Dependent Vegetation. As discussed in Appendix F.10, increased flows up to 5.6 cfs will not significantly affect amphibians or benthic macro invertebrates. Please see Master Response 36 - Flows in South Fork Wolf Creek.

## Response to Comment Agcy 1-47

The commenter states that the Empire Mine Park should be considered a sensitive receptor for the purpose of assessing noise and vibration impacts, and also states that it is concerned that noise and vibration could impact wildlife at the park. The commenter is correct that the nearest trail within the Empire Mine SHP is approximately 850 feet from the boundary of the Brunswick Site. However, the distance from that nearest trail to the proposed project's noise-generating operations within the Brunswick Site is over 2,500 feet. And while the Bennet Street Grasslands are approximately 900 feet south of the Centennial Site, the nearest trail within the Empire Mine SHP is approximately 2,250 feet from the nearest proposed noise-generating activities within the Centennial Site. Because other sensitive receptors located much closer to the noise-generating aspects of the proposed project were evaluated and determined to be less than significantly impacted by project noise generation, and noise/vibration diminish by distance form the source, it follows that more distant receptors, including the Empire Mine SHP trail network, would similarly be less than significantly impacted by project noise generation. Examination of DEIR Figures 4.10-7 and 4.10-8 indicate that both daytime and nighttime noise generation of operations at the Brunswick Site would be well below 40 dBA at the Empire Mine site. DEIR Table 4.10-4 (General Plan Noise Element Exterior Noise Limits) shows that the County's noise standard applicable to recreation use is 70 dBA $L_{eq}$ during the hours in which the park would be open to the public (i.e., 7 am - 7 pm). Therefore, the predicted project noise level of less than 40 dBA at the park site from Brunswick operations would be more than 30 dBA below the County's noise standard applicable to recreation uses. At the portions of the Empire Mine SHP nearest to the Centennial Site, predicted daytime noise levels are 27 dBA at the grasslands and 22 dBA at the nearest trail within the park. These predicted noise levels at both locations are well below the County's 70 dBA daytime noise level standard. As a result, the Empire Mine SHP would not be adversely impacted by noise from operations at the Centennial Site. This level of noise is significantly lower than the current daytime ambient noise in the grasslands area which is estimated to be 53 decibels ($L_{eq}$) at receptor location #8, located on the eastern boundary of the Bennett Street Grasslands and to be 58 decibels ($L_{eq}$) at receptor location #9 located near the “upstream reach” of the park. See Table 6 and Figure 3 of Appendix L in the DEIR. As stated on page 4.4-74 of the DEIR, in general, wildlife species have been shown to acclimate to the noise environment in which the species resides. Wildlife species in proximity to the E. Bennett Road would be considered acclimated to noise levels associated with greater sound levels as would be created by the activities at the Centennial site.

## Response to Comment Agcy 1-48

Please see Response to Comment Agcy 1-26 above. The analysis of Impact 4.10-1 in the DEIR considers the noise impact to be significant and unavoidable to human sensitive receptors and not wildlife. As shown in Figure 3 and 4 of Appendix L, Sensitive Receptor Site 9 is between ambient noise and vibration measurements sites 7 and 8. The average ambient noise (Leq) at these sites during daytime hour ranges from 54 to 59 decibels as shown in Table 1 of Appendix L and the predicted noise from the construction of the potable water pipe along E. Bennett Road is predicted to be 58 decibels at receptor site 9. This is similar to the existing ambient noise from traffic at this location. As stated on page 4.4-74 of the DEIR, studies of the effects of noise on wildlife populations have shown that while some species can be negatively affected by traffic

noise and wildlife densities are generally inversely proportional to distance from roadways, many species of wildlife are unaffected by roadway noise. In general, wildlife species have been shown to acclimate to the noise environment in which the species resides. Wildlife species in proximity to the E. Bennett Road would be considered acclimated to noise levels associated with similar sound levels as would be created by the temporary construction activities for the pipeline.

## Response to Comment Agcy 1-49

The commenter states that diesel fuel storage and use of numerous flammable chemicals daily by the project was not fully evaluated in the DEIR and that these constituents are inherently dangerous and can exacerbate wildfire if improperly handled and/or released. The commenter does not provide specifics as to why the DEIR does not fully evaluate these issues. Chapter 4.7 of the DEIR analyses hazardous materials and has proposed Mitigation Measures 4-7(a) through (d) which would reduce the risk from transport, storage, and use of hazardous materials to a less than significant level. Chapter 4.13 of the DEIR discuss and analyzes wildfire risk attributable to the proposed project. Please see Master Response 6 – Wildfire Impacts.

The commenter states that fuel treatment projects that have occurred in the Union Hill area of the Empire Mine State Historic Park from 2014-2021, located 450 feet west and uphill of the Brunswick site, are not included in Figure 4.13-2 of the DEIR. This comment is noted. The inclusion of this information would not change the significance conclusions of the DEIR in regard to wildfire**.**

## Response to Comment Agcy 1-50

The park boundary and elevations have been added to Sheet #16, attached to the Final EIR as Appendix L. The elevation in this area is similar to wells in the Beaver Drive area and Cedar Ridge Area (W140-W144).

As shown in Table 4-2 of Appendix K.2, the depth to water (well depth minus water column) is estimated to average between 45 ft to 78 ft. As shown in Table 4-4 of Appendix K.2, the depth to water is estimated to average 40 feet in the Cedar Ridge area. The typical seasonal water level fluctuations for wells in the Beaver Drive area (1995 Well ID 4, 6, 7, 21, 85) are approximately 25 ft as shown in the hydrographs in Appendix B of Appendix K.2.

The depth to groundwater and seasonal fluctuation in this area of the Park is therefore consistent with the description provided in the DEIR. As discussed on page 4.13-21 of the DEIR, the depth to groundwater generally mimics the topography, but the depth is greater under ridges and drainage divides and closer to the surface near creeks and valleys. In the areas away from the creeks and valleys, the depth to groundwater is typically greater than 10 feet and, in many cases, may be 100 feet or more. In addition, the normal seasonal fluctuation in the depth to groundwater may be 10 feet to 30 feet or more. Thus, in the areas away from the creeks, the existing groundwater surface is below the typical depth of rooted vegetation and tap roots from trees, especially during the drier months when the depth to groundwater is at its greatest.

As discussed in Master Response 33, it should be noted that the root depths referred to in Appendix K.2 represent extreme cases and the analysis of impact to vegetation is therefore conservative. The terrestrial vegetation in the project area, including trees present in the Empire Mine State Park, have roots depths typically less than 6 feet, which is well within the unsaturated zone above the groundwater table. Please see Master Response 33 – Groundwater Dependent Vegetation.

## Response to Comment Agcy 1-51

The park boundary and elevations have been added to Sheet #16, attached to the Final EIR as Appendix L. As shown, the simulated ground water drawdown for the flat meadow area north of South Fork Wolf Creek (the "valley bottom") is outside of the 1-foot drawdown contours and would be less than 1 foot of drawdown, and therefore negligible. The Ground Water Model did not simulate recharge from the additional mine water discharge and therefore the drawdown contours shown are conservative in the area adjacent to the creek. Please see Master Response 33 – Groundwater Dependent Vegetation.

## Response to Comment 1-52

Groundwater drawdown and the impact to vegetation was discussed on pages 4.13-21 and page 4.13-21 in the DEIR. Please see Master Response 33 – Groundwater Dependent Vegetation.

Matt Kelley
Senior Planner
County of Nevada
950 Maidu Ave
Nevada City, CA 95959

**Idaho Maryland Mine – Rise Grass Valley**

Dear Matt:

Thank you for including the California Department of Transportation (Caltrans) in the Initial Consultation review process for the project referenced above. The mission of Caltrans is to provide a safe, sustainable, integrated and efficient transportation system to enhance California's economy and livability. The Local Development-Intergovernmental Review (LD-IGR) Program reviews land use projects and plans through the lenses of our mission and state planning priorities of infill, conservation, and travel-efficient development. To ensure a safe and efficient transportation system, we encourage early consultation and coordination with local jurisdictions and project proponents on all development projects that utilize the multimodal transportation network.

**Agcy 2-1**

The proposed project of a combined application for a Conditional Use Permit and Reclamation Plan to re-initiate underground mining and gold mineralization processing of the Idaho-Maryland Mine within unincorporated Western Nevada County. The proposed project would be located on two properties owned by Rise Grass Valley is requesting comment on a Draft Environmental Impact Report (DEIR). The following feedback is based on the provided DEIR.

***Traffic Operations – Highway Operations***

**Agcy 2-2**

The applicant should specify if a portion of mitigation fees will be allocated for improvements at the State Route 20 (SR 20) on/off-ramps. With other future development in the area, Nevada County should continue to coordinate with Caltrans to determine appropriate solution(s) to the existing intersection at Brunswick Road and SR 174, which operates at LOS E per the Draft EIR in the SB direction on Brunswick Road in the PM peak hour.

***Hydraulics***

**Agcy 2-3**

The Watersheds areas on section 4.8 seem smaller than what the online USGS tool StreamStats found the Upper Wolf Creek and South Fork Wolf Creek at 2816 acres and 1472, respectively.

"Provide a safe and reliable transportation network that serves all people and respects the environment"

**Agcy 2-4**

The 566 acre difference seems to be from StreamStats including an area NW SR-49. Please clarify why is there no consolidated document of all mitigations the draft EIR states on pages 4.8-52, 4.10-37, 4.10-45, and 4.10-58.

**Agcy 2-5**

The 200 heavy truck trips per day for transporting mining material (See page 4.10-35 of the Draft EIR) were not analyzed for impact to Hwy 49 or local roads for the lifespan of the road structure. The roads used by these trucks could potentially decrease the lifespan of the roadways.

**Agcy 2-6**

Please provide our office with copies of any further actions regarding this project or future development of the property. We would appreciate the opportunity to review and comment on any changes related to this development.

If you have any questions regarding these comments or require additional information, please contact Colin Fredrickson, by phone (530) 812-5049 or via email to colin.fredrickson@dot.ca.gov.

Sincerely,

Kevin Yount

KEVIN YOUNT, Branch Chief
Office of Transportation Planning
Regional Planning Branch—East

"Provide a safe and reliable transportation network that serves all people and respects the environment"

## AGENCY LETTER 2: KEVIN YOUNT, CALIFORNIA DEPARTMENT OF TRANSPORTATION

### Response to Comment Agcy 2-1

This is an introductory comment and does not address the DEIR. Comment noted.

### Response to Comment Agcy 2-2

As stated on page 4.12-24 of the DEIR, The Nevada County Transportation Commission, in partnership with Nevada County, Nevada City, and the City of Grass Valley, established the Regional Transportation Mitigation Fee (RTMF) program in 2001. Under the RTMF program, development impact fees are collected to help fund construction of the regional system of roads, streets, and highways needed to accommodate growth in western Nevada County. The purpose of the RTMF is to establish a uniform, cooperative program to mitigate the cumulative indirect regional impacts of future developments on traffic conditions of regional roadways in Nevada County. The fees help fund improvements needed to maintain the target LOS in the face of the higher traffic volumes brought on by new developments.

The proponent would be required to pay the required RTMF based on the total thousand square feet of buildings constructed at the specified fee at the time of construction (see Mitigation Measure 4.12-1(a)). The allocation of these funds would be allocated to projects by the RTMF. Such allocations could include State Route 20 on/off ramps; however, the allocation of these funds would depend on the projects and priorities of the RTMF.

It is also noted that Mitigation Measure 4.12-1(b) of the DEIR requires the applicant to enter into a Traffic Mitigation Agreement with the County regarding the SR 174/Brunswick Road intersection. The Agreement shall require the applicant to pay the project's fair share contribution toward the improvements necessary to improve intersection operations to an acceptable level.

### Response to Comment Agcy 2-3

Sheet 16 shows this missing area and is attached to the Final EIR as Appendix L. The area of the Upper Wolf Creek watershed on page 4.8-2 of the DEIR is hereby corrected to state the area at 2,820 acres.

> **Regional Hydrology**
>
> The project sites are located within two watershed areas. The Centennial Industrial Site is located in the Upper Wolf Creek watershed, which encompasses approximately ~~2,250~~2,820 acres upstream from the western end of the Centennial Industrial Site. The Brunswick Industrial Site is located in the South Fork Wolf Creek watershed, which encompasses approximately 1,450 acres and is upstream of a culvert where the creek passes underneath part of the City of Grass Valley.

The stated area of the South Creek Wolf Creek watershed of 1,450 acres is similar to the streamstats report from USGS. These watershed areas presented in Appendix K.2 are not used the analysis of the DEIR and therefore no other changes are required. Hydraulic analysis by Nevada City Engineering, Itasca, and Balance used the assumptions of watershed areas as stated in those technical reports.

### Response to Comment Agcy 2-4

The consolidated mitigations are presented in Table 2-1, Summary of Impacts and Mitigation Measures, of the DEIR, and Chapter 4, Mitigation Monitoring and Reporting Program, of this Final EIR.

## Response to Comment Agcy 2-5

The location of traffic counts used in the traffic analysis were vetted and approved by the Nevada County Public Works Department. Class and Volume counts were not conducted on SR49 or the ramps from Brunswick Road to the highway, which would allow a Traffic Index to be calculated. Furthermore, the Nevada County Traffic Impact Analysis Guidelines do not require an analysis of Traffic Index or impacts to lifespan of roadways. Truck traffic on state highway infrastructure is not an incompatible use that requires analysis under CEQA. Therefore, the analysis requested is not required for the EIR.

## Response to Comment Agcy 2-6

Comment noted. Nevada County will provide the commenter with notifications regarding the proposed project.

Idaho.MMEIR@co.nevada.ca.us

Dear Mr. Kelley:

Subject: IDAHO-MARYLAND MINE PROJECT
DRAFT ENVIRONMENTAL IMPACT REPORT (DEIR)
SCH# 2020070378

The California Department of Fish and Wildlife (CDFW) received and reviewed the Notice of Availability of a DEIR from Nevada County Planning Department (County) for the Idaho-Maryland Mine Project (Project) pursuant the California Environmental Quality Act (CEQA) statute and guidelines.[1]

Thank you for the opportunity to provide comments and recommendations regarding those activities involved in the Project that may affect California fish, wildlife, native plants, and their habitat. Likewise, we appreciate the opportunity to provide comments regarding those aspects of the Project that CDFW, by law, may need to exercise its own regulatory authority under the Fish and Game Code.

**Agcy 3-1**

**CDFW ROLE**

CDFW is California's **Trustee Agency** for fish and wildlife resources, and holds those resources in trust by statute for all the people of the State (Fish & G. Code, §§ 711.7, subd. (a) & 1802; Pub. Resources Code, § 21070; CEQA Guidelines § 15386, subd. (a)). CDFW, in its trustee capacity, has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species. (Fish & G. Code., § 1802.) Similarly for purposes of CEQA, CDFW provides, as available, biological expertise during public agency environmental review efforts, focusing specifically on projects and related activities that have the potential to adversely affect fish and wildlife resources.

CDFW is also submitting comments as a **Responsible Agency** under CEQA. (Pub. Resources Code, § 21069; CEQA Guidelines, § 15381.) CDFW expects that it may need

[1] CEQA is codified in the California Public Resources Code in section 21000 et seq. The "CEQA Guidelines" are found in Title 14 of the California Code of Regulations, commencing with section 15000.

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

to exercise regulatory authority as provided by the Fish and Game Code. As proposed, for example, the Project is subject to CDFW's lake and streambed alteration regulatory authority. (Fish & G. Code, § 1600 et seq.) Likewise, to the extent implementation of the Project as proposed may result in "take" as defined by State law of any species protected under the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.), related authorization as provided by the Fish and Game Code is recommended. CDFW also administers the Native Plant Protection Act, Natural Community Conservation Act, and other provisions of the Fish and Game Code that afford protection to California's fish and wildlife resources.

**PROJECT DESCRIPTION SUMMARY**

The Project's surface components will be located on approximately 175.64 acres consisting of the Brunswick Industrial Site, the Centennial Industrial Site, and a 0.30-acre portion of East Bennett Road for off-site improvements associated with a potable water pipeline easement. The Project would also involve underground mining within an approximately 2,585-acre mineral rights boundary owned by the Rise Grass Valley.

**Agcy 3-2**

The Project consists of re-initiating underground mining and gold mineralization processing for the Idaho-Maryland Mine over an 80-year period. Following completion of mining and processing activities, the Project sites would be reclaimed to open space and industrial uses. The Project would involve: (1) dewatering of the underground mine workings; (2) construction and operation of aboveground processing and water treatment facilities at the Brunswick Industrial Site; (3) engineered fill placement for potential future industrial pad development at the Centennial and Brunswick Industrial Sites; (4) installation of a potable water pipeline for residential potable water supply; and (5) reclamation of the Project sites in accordance with the Project's proposed Reclamation Plan. From the total of 175.64 acres included in the Project sites, approximately 104 acres would be disturbed as a result of construction of the facilities proposed to support dewatering, mining, and processing at the Idaho-Maryland Mine, as well as engineered fill placement.

**COMMENTS AND RECOMMENDATIONS**

CDFW offers the comments and recommendations below, in addition to the comments in Attachment 1, to assist the County in adequately identifying and, where appropriate, mitigating the Project's significant, or potentially significant, direct, and indirect impacts on fish and wildlife (biological) resources.

**Agcy 3-3**

CDFW is primarily concerned with the Project impacts to existing fish and wildlife resources including brown trout (*Salmo trutta*), foothill yellow-legged frog (*Rana boylii*) (FYLF), California red legged frog (*Rana draytonii*), Pine Hill flannelbush (*Fremontodendron californicum ssp. decumbens*), California black rail (*Laterallus jamaicensis coturniculus*), willow flycatcher (*Empidonax traillii*), and other aquatic and terrestrial plant and wildlife species. CDFW is also concerned with impacts from the discharge of water on riparian habitat, impacts to downstream aquatic resources from mining activities, and dewatering impacts on water temperature, nutrient concentrations, and turbidity. CDFW provides the attached and following comments for the County's consideration:

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

**Agcy 3-4**

1. On page 2-30, Measure 4.4-1(a) for Pine Hill flannelbush (*Fremontodendron californicum ssp. decumbens)* lists Project-specific mitigation measures to be implemented on the Centennial Industrial Site. Some of these measures include seed collection, transplantation, and creating a Habitat Management Plan (HMP). Pine hill flannelbush is listed as rare under the Native Plant Protection Act (NPPA) (Fish & G. Code § 1900 et seq.). The NPPA prohibits the take or possession of state-listed rare and endangered plants, including any part or product thereof, unless authorized by CDFW or in certain limited circumstances. Please see comment 3 for Incidental Take Permit (ITP) recommendations.

**Agcy 3-5**

2. On page 2-34, two of the special status plants that mitigation measure 4.4-1(b) refers to, are listed as state endangered, the Stebbin's morning glory (*Calystegia stebbinsii*) and the Scaddel Flat checkerbloom (*Sidalcea stipularis*). Measures indicated to be included in the HMP as currently described in the DEIR would result in take. Measures resulting in take include, but are not limited to, on page 2-37 *"remove bulbs of individual plants to be directly impacted during the dormant season; relocate the bulbs to a site with similar soil, hydrologic, vegetation type and aspect as the portion of the project site where the plants are found; and identify the location(s) for dormant season relocation and site selection for transplantation."* As stated above, take of state-listed plants due to Project activities may only be permitted under an appropriate CESA take authorization. Please see comment 3 for ITP recommendations.

**Agcy 3-6**

Additionally, the DEIR should cover a range of possibilities for mitigation. The use of relocation, salvage, and/or transplantation as the sole mitigation for impacts to rare, threatened, or endangered species are generally experimental in nature and largely unsuccessful. Therefore, the DEIR should describe additional mitigation measures utilizing habitat restoration, conservation, and/or preservation, in addition to avoidance and minimization measures, if it is determined that there may be impacts to rare, threatened, or endangered species.

**Agcy 3-7**

3. CDFW recommends that an ITP be obtained where the Project has the potential to result in take of a species state-listed as rare, candidate, threatened, or endangered under CESA or NPPA, either through construction or over the life of the Project. Plant species not listed as rare, threatened, endangered, or candidates for listing under CESA or NPPA may nevertheless meet the definition of rare or endangered provided in CEQA (Cal. Code Regs., tit. 14, § 15380, subd. (b).). Please note that mitigation measures that are adequate to reduce impacts to a less-than significant level to meet CEQA requirements may not be enough for the issuance of an ITP. To issue an ITP, CDFW must demonstrate that the impacts of the authorized take will be minimized and fully mitigated (Fish & G. Code § 2081 (b)). To facilitate the issuance of an ITP, CDFW recommends the DEIR include species specific measures to minimize and fully mitigate the impacts to any state-listed species the Project activities have the potential to take.

**Agcy 3-8**

4. On page 2-38, the FYLF pre-construction survey and avoidance and minimization measures as laid out in measure 4.4-2(a), details Visual Encounter Surveys (VES) to be conducted. However, given that there are sightings of FYLF within five miles, both to

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

the north at Deer Creek, and to the East at Greenhorn Creek, the limited historic survey data available in the immediate Project vicinity, and the lack of information regarding the distribution and extent of the current FYLF population within the Project area, CDFW recommends FYLF surveys and habitat assessments be conducted throughout the Project Study Area and include the results in the DEIR. CDFW recommends that surveys be conducted in accordance with CDFW's *Considerations for Conserving the Foothill Yellow-Legged Frog* (2018), available here: https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=157562&inline. CDFW recommends the following survey and species considerations be incorporated into the DEIR for Project implementation:

a. As described in the CDFW's *Considerations for Conserving the Foothill Yellow-Legged Frog* (2018) document, VES conducted during the late summer are often the easiest method for determining presence; subadults and occasionally adults are often observed along river margins, and subadult and adult frogs will likely also be observed in tributary streams (Crump and Scott 1994).

b. To increase the likelihood of detection, surveys should include at least one VES during the breeding and/or oviposition period (generally April – June), a tadpole survey four to eight weeks after the breeding survey(s), a subadult survey in late summer/early fall (generally late August to early October), and a final VES within 3 to 5 days prior to starting work.

    i. It is important to understand that frogs are ectothermic, so ambient temperature affects the likelihood of detection. Whether the life form is larval or subadult, both stages will shelter in place under substrate and emerge and become active with warmth (i.e., detection probability increases with temperature).

c. If a survey fails to detect foothill yellow-legged frogs within suitable habitat, a follow-up survey should be conducted two to four weeks after the initial survey.

d. Develop measures to avoid incidental take on a site- and project-specific basis.

    i. For example, measures may vary based on the type and extent of disturbance, duration and timing of disturbance, and influence of environmental factors. A season of operation that completely avoids foothill yellow-legged frog presence does not exist; if frogs are present and breeding, they may be encountered in various life stages year-round. However, in locations having periodic dry conditions, especially prolonged dry conditions, foothill yellow-legged frogs are unlikely to be encountered. Under dry conditions, foothill yellow-legged frogs usually seek refuge in wetted tributaries (or any wetted feature).

**Agcy 3-9**

In March 2020, the California Fish and Game Commission recognized two clades of the FYLF (*Rana boylii*) as threatened under the CESA. The Northeast/Northern Sierra clade was one of those clades. Therefore, please revise Table 4.4-6 to reflect Foothill

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

yellow-legged frog status as threatened under CESA. Please see comment 3 for ITP recommendations.

5. On pages 2-43 through 2-45, the California black rail 4.4-2(d) pre-construction survey and avoidance and minimization measures indicate that a call-back/response survey will be done to detect evidence of this species. The California black rail is a fully protected species (Fish & G. Code § 3511). Fully protected species may not be taken or possessed at any time. The DEIR should state that the qualified biologist will obtain the proper permits prior to implementing call-back/response surveys. This may include the need for a Memorandum of Understanding (Fish & G. Code § 2081(a)) from CDFW prior to conducting the surveys to ensure the species scientific research is executed appropriately and the data is reported accurately.

**Agcy 3-10**

Project activities described in the DEIR should be designed to completely avoid any fully protected species that have the potential to be present within or adjacent to the Project area. CDFW also recommends the DEIR fully analyze potential adverse impacts to fully protected species due to habitat modification, loss of foraging habitat, and/or interruption of migratory and breeding behaviors. CDFW recommends that the County include in the analysis how appropriate avoidance, minimization, and mitigation measures will reduce indirect impacts and avoid take of fully protected species.

6. The DEIR has identified perennial, intermittent, and ephemeral rivers, streams, and other hydrologically connected aquatic features. The DEIR did not analyze all potential temporary, permanent, direct, indirect and/or cumulative impacts to the above-mentioned aquatic features and associated biological resources/habitats that may occur because of the Project. Therefore, the DEIR should propose appropriate avoidance, minimization and/or mitigation measures to reduce impacts to a less-than-significant level including but not limited to Project impacts to water temperature, water nutrient concentrations, and turbidity.

**Agcy 3-11**

The DEIR has identified Project activities that will require notification to CDFW pursuant to Section 1602 of the Fish and Game Code. Notification is required for any activity that may do one or more of the following:

- Substantially divert or obstruct the natural flow of any river, stream, or lake,
- Substantially change or use any material from the bed, channel or bank of any river, stream, or lake; or
- Deposit debris, waste, or other materials where it may pass into any river, stream or lake.

Please note that "any river, stream or lake" includes those that are episodic (i.e., those that are dry for periods of time) as well as those that are perennial (i.e., those that flow year-round). This includes ephemeral streams and watercourses with a subsurface flow. It may also apply to work undertaken within the flood plain of a body of water. Upon receipt of a complete notification, CDFW will determine if the Project activities may substantially adversely affect existing fish and wildlife resources and whether a Lake and Streambed Alteration (LSA) Agreement is required. The Project as currently

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

proposed in the DEIR will require a LSA Agreement. A LSA Agreement will include measures necessary to protect existing fish and wildlife resources.

CDFW's issuance of a LSA Agreement is a "project" subject to CEQA (see Pub. Resources Code 21065). To facilitate issuance of a LSA Agreement, the DEIR should fully identify the potential impacts to the lake, stream, or riparian resources, and provide adequate avoidance, minimization, mitigation, and monitoring and reporting commitments.

7. The DEIR does not include a discussion of the Project's effects of mining operations on resident fish in Wolf Creek or South Fork Wolf Creek. On March 8, 2022, CDFW staff performed a spot electrofishing survey within South Fork Wolf Creek. The survey included three electrofishing locations within Reaches C and D as shown in Appendix K.1, Figure A1, of the DEIR. The efforts identified the presence of multiple life stages of resident brown trout (*Salmo Trutta*) at each of the survey locations (Memorandum: Electrofishing at South Fork Wolf Creek, Nevada County, March 8, 2022). The DEIR should discuss resident fish in South Fork Wolf Creek and Wolf Creek and analyze potential fisheries impacts that may occur as a result of the Project and propose ways to avoid, minimize, or mitigate any potentially significant impacts to a less-than-significant level.

**Agcy 3-12**

8. In Appendix K-2, the DEIR estimates that initial dewatering will involve pumping groundwater from the mine works at a rate of approximately 2,500 gallons per minute (gpm) for six months, with ongoing dewatering of 850 gpm during mine operation. As a result of the dewatering, there is a predicted groundwater drawdown of up to 10 feet. The DEIR identifies the different types of vegetation within the Project site, including riparian vegetation, but does not characterize the vegetation's potential reliance on groundwater or interconnected surface waters. The DEIR does not include a discussion of the potential impacts of lowering the groundwater table on environmental users of groundwater, such as groundwater dependent ecosystems or environmental users of interconnected surface waters.

Page 121 of Appendix K.2 of the DEIR states that in higher topographic areas, the depth to groundwater is already below typical rooting depths and that in lower areas, the flow releases to South Fork Wolf Creek would increase recharge to support groundwater levels. Appendix K.2 does not provide sufficient detail about the location of vegetation that may be reliant on groundwater or interconnected surface waters, the depth to groundwater underlying those areas, or evidence that increased flows in South Fork Wolf Creek would provide enough groundwater recharge to maintain groundwater

levels to support existing vegetation. Additionally, Appendix K.2 states that because projected groundwater drawdown is within the range of historic fluctuations, impacts would be less-than-significant. However, maintaining groundwater at the projected maximum drawdown level, or any reduced groundwater level, for sustained mine operations over 80 years without the reprieve of historical seasonal groundwater highs may result in temporary or permanent impacts to environmental users of groundwater, including groundwater dependent vegetation.

**Agcy 3-13**

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

The DEIR should include a more detailed analysis of the impacts of initial and continued dewatering on environmental users of groundwater, including groundwater dependent ecosystems and users of interconnected surface waters. The analysis should include figures displaying the locations of potential groundwater dependent ecosystems or riparian or other vegetation that relies on interconnected surface waters, the depth to groundwater underlying the groundwater dependent ecosystems and riparian vegetation in Project and non-Project scenarios, and additional discussion of the projected increase in recharge as a result of the discharge of treated water into South Fork Wolf Creek, including the interconnectivity between groundwater and South Fork Wolf Creek surface water. If this more detailed analysis identifies any potentially significant impacts, the DEIR should state how the Project will avoid, minimize, or mitigate any these impacts to a less-than-significant level.

9. The DEIR does not discuss Project impacts on water temperature in South Fork Wolf Creek or Wolf Creek. Initial and continued dewatering of the mine works will reduce groundwater discharge into the surface water bodies where groundwater-surface water connectivity exists in proximity to the mine. Groundwater inflows to surface water typically maintain lower surface water temperatures. Where mine operations reduce groundwater contributions to South Fork Wolf Creek by altering the subsurface hydraulic gradients, mine operations can impact creek temperature. The DEIR should analyze the impacts of mine dewatering on surface water temperature in South Fork Wolf Creek and Wolf Creek and the aquatic species therein. If this analysis identifies any potentially significant impacts, the DEIR should state how the Project will avoid, minimize, or mitigate any these impacts to a less-than-significant level.

**Agcy 3-14**

The DEIR also does not discuss the temperature of the on-site treated water that will be discharged into South Fork Wolf Creek, which has the potential to significantly alter instream temperatures and affect resident aquatic species, including brown trout (see above comment on resident fish). The DEIR should include an analysis of Project impacts on instream water temperatures of South Fork Wolf Creek and Wolf Creek. The analysis should consider both the temperature of on-site treated water discharges into South Fork Wolf Creek as well as the projected reduction of groundwater discharges to baseflow in the surface water bodies. If this analysis identifies any potentially significant impacts, the DEIR should state how the Project will avoid, minimize, or mitigate any these impacts to a less-than-significant level.

10. The DEIR states that the Project, in combination with the cumulative list of projects, would result in a less-than-significant cumulative impact to water quality, drainage patterns, and groundwater resources. The cumulative impacts discussion does not include a discussion of the impacts to environmental users of groundwater, habitats, or aquatic resources that would occur during the 80-year operational timeline for the Project. The 80-year duration of the Project would essentially create a new hydrologic baseline in the Project area and in upstream and downstream interconnected hydrology. The DEIR does not discuss the shifting ecological baseline that would occur during the Project, nor does it account for impacts that would occur at the end of the Project or the restoration timeline for a return to the pre-Project baseline conditions.

**Agcy 3-15**

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

The cumulative impacts discussion should consider the ecological impacts of the 80-year Project implementation timeline and the resulting adaptation of ecosystems and species to long-term altered hydrology. The DEIR should also evaluate impacts to hydrology in the Project area during the period of time in which recharge is refilling the previously dewatered mine works for potential impacts to surface water bodies, aquatic species, and groundwater dependent and riparian vegetation.

Agcy 3-16

11. South Fork Wolf Creek and Wolf Creek are tributary to the Bear River, which has existing beneficial uses of warm and cold freshwater habitat, and wildlife habitat. The DEIR does not discuss potential downstream impacts to the Bear River and its beneficial uses as a result of the Project and associated impacts on upstream hydrology. The DEIR should discuss and assess potential downstream impacts to the Bear River and its existing beneficial uses.

Agcy 3-17

Please see *Attachment 1: Additional CDFW Comments on Idaho-Maryland Mine DEIR April 4, 2022*, for all additional CDFW comments on this DEIR.

**ENVIRONMENTAL DATA**

Agcy 3-18

CEQA requires that information developed in environmental impact reports and negative declarations be incorporated into a database which may be used to make subsequent or supplemental environmental determinations (Pub. Resources Code, § 21003, subd. (e)). Accordingly, please report any special-status species and natural communities detected during Project surveys to the California Natural Diversity Database (CNDDB). The CNNDB field survey form can be found at the following link: https://www.wildlife.ca.gov/Data/CNDDB/Submitting-Data. The completed form can be submitted online or mailed electronically to CNDDB at the following email address: CNDDB@wildlife.ca.gov.

**FILING FEES**

Agcy 3-19

The Project, as proposed, would have an impact on fish and/or wildlife, and assessment of filing fees is necessary. Fees are payable upon filing of the Notice of Determination by the Lead Agency and serve to help defray the cost of environmental review by CDFW. Payment of the fee is required in order for the underlying project approval to be operative, vested, and final. (Cal. Code Regs, tit. 14, § 753.5; Fish & G. Code, § 711.4; Pub. Resources Code, § 21089.)

**CONCLUSION**

Agcy 3-20

Pursuant to Public Resources Code §21092 and §21092.2, CDFW requests written notification of proposed actions and pending decisions regarding the proposed Project. Written notifications shall be directed to: California Department of Fish and Wildlife North Central Region, 1701 Nimbus Road, Rancho Cordova, CA 95670 or emailed to r2CEQA@wildlife.ca.gov.

DocuSign Envelope ID: B473E941-3313-44A0-9A12-16EE9383CDE6

CDFW appreciates the opportunity to comment on the DEIR to assist in identifying and mitigating Project impacts on biological resources. CDFW personnel are available for consultation regarding biological resources and strategies to minimize and/or mitigate impacts. Questions regarding this letter or further coordination should be directed to Caitlyn Oswalt, Environmental Scientist at (916)358-4315 or Caitlyn.Oswalt@wildlife.ca.gov.

Sincerely,

DocuSigned by:

| | Attachment 1: Additional CDFW Comments on Idaho-Maryland Mine DEIR April 4, 2022 | | | | | |
|---|---|---|---|---|---|---|
| | Comment # | Section | Print Page # | PDF Page # | Issue / Comment | Solution / Suggested Fix |
| Agcy 3-21 | 1 | 2 | 1-2 | 32 | Under the Project Components section, it says "the proposed project would reinitiate underground mining and gold mineralization processing for the Idaho-Maryland Mine over an 80-year permit with gold mineralization processing and underground exploration and underground exploration and mining proposed to operate 24 hours a day, 7 days a week during full operations." | Please specify which permit or permits that are being referred to in this statement. |
| Agcy 3-22 | 2 | 2 | 2-3 | 53 | The DEIR does not include details on what developments are proposed within the Management Plan to allow for development within the required 100-foot setback from the Riparian Areas of the Perennial Watercourses, pursuant to the Nevada County LUDC, Section L-II 4.3.17, at the Brunswick and Centennial Industrial Sites. | CDFW recommends to detail what development is proposed and the impacts those development projects will have on Wolf Creek, South Forth Wolf Creek, the communities that rely on these waterways, and the riparian vegetation. |
| Agcy 3-23 | 3 | 2 | 2-31 | 81 | Mitigation measure 4.4-1(a) for Pinehill flannelbush (*Fremontodendron californicum ssp. decumbence* ) details in the event project actions that will directly impact Pinehill flannelbush, seed collection and banking will be done to ensure the future replacement and recovery efforts pursuant to the requirements of Section 6.2 of the HMP. | Please clarify when and how many seeds will be collected. Once the seeds have been collected, which seed bank will be used and how long will they be stored? |
| Agcy 3-24 | 4 | 2 | 2-36 | 86 | In mitigation measure 4.4-1(b) it states:<br>"weekly site monitoring by a qualified biologist to ensure that the special-status plants are being protected during site disturbance and construction." | CDFW recommends revising this to, "A qualified biologist shall be onsite during all vegetation and ground disturbing activities that are within the vicinity of special status plants and weekly monitoring of the protective fencing along the buffer zone." This will help ensure that special-status plants are being protected during site disturbance and construction. |
| Agcy 3-25 | 5 | 2 | 2-38 | 88 | There are multiple CNPS listed plants with a ranking of 1B with the potential to occur within the Project site. In mitigation measure 4.4-1(b) for Other Special-Status Plant Species it states:<br>"If the 80 percent survival is not established after two years, transplants of individuals grown from seed shall be planted at a location with similar soil, hydrologic, vegetation type and aspect as the portion of the site where they are found. Transplantation shall occur in the season deemed to have the greatest potential for success, generally the fall, after rains have commenced. Transplants shall be monitored every month for the first six months, then every two months for a minimum of two years. After two summer seasons of monitoring identifies successful establishment of 50 percent of the initial transplants, transplant seedlings will be deemed successful." | Measure 4.4-1(b) applies to multiple special status plant species with a CNPS ranking of 1B with the probability to occur within the project site. Therefore, CDFW recommends the DEIR detail species specific measures and success criteria that will result in no net loss for all special status species. CDFW recommends the Qualified Biologist obtains a scientific collecting permit for any special status plant species that may be impacted by this project. Plant species not listed as rare, threatened, endangered, or candidates for listing under CESA or NPPA may meet the definition of rare or endangered provided in CEQA (Cal. Code Regs., tit. 14, § 15380, subd. (b).). |
| Agcy 3-26 | 6 | 2 | 2-40 | 90 | 4.4-2(b) Western Pond Turtle Pre-construction survey and avoidance and minimization measures. | The western pond turtle (*Actinemys marmorata*) is a species of special concern. Movement out of harm's way must be authorized by CDFW under a scientific collecting permit or a Lake and Streambed Alteration Agreement. The DEIR should state that the Qualified Biologist should have all required permits before commencing species specific surveys. |
| Agcy 3-27 | 7 | 2 | 2-46 | 96 | Coast Horned Lizard 4.4-2(e) "...If the species is documented during pre-construction survey(s), a qualified wildlife biologist (approved by CDFW) shall move individual coast horned lizards outside of the proposed disturbance area(s) in order to avoid an impact to this species." | For species of special concern, a Scientific Collecting Permit may be required to move individual Coast Horned Lizards out of harm's way. The DEIR should state that the Qualified Biologist should have all required permits before commencing species specific surveys. |
| Agcy 3-28 | 8 | 2 | 2-47 | 97 | Pre-construction surveys for special-status bats in measure 4.4-2(f) should keep in mind the time of year and avoid starting construction in sensitive bat habitat during maternal rooting season. | To reduce the biological impacts to special status bat species, CDFW recommends conducting bat surveys between March 1 to July 31 by a qualified biologist with experience with bats in the year prior to the removal of any oak trees, buildings and structures, or dewatering of the mines. Bats are at their most vulnerable in buildings during the summer, when large numbers may be gathered together and young bats, unable to fly, may be present. Operations to known breeding sites should therefore be timed to avoid the summer months, therefore work should be sufficiently advanced by May or June for returning bats to be dissuaded from breeding in that site for that year. If no bat roosts are detected, then no further action is required if the trees are removed prior to the next breeding season. If removal is delayed, then an additional pre-construction survey shall be conducted 30 days prior to removal to ensure that a new colony has not established itself. |

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Agcy 3-29 | | 9 | 2 | 2-47 | 97 | Special-Status Bats 4.4-2(f) "...Furthermore, if a maternal (breeding) roost is documented, no disturbance shall occur until the breeding roost has dispersed from the structure or riparian and forested woodlands they are found in." | In order to ensure the maternal roost has fully dispersed CDFW recommends changing this language to: "...Furthermore, if a maternal (breeding) roost is documented, no disturbance shall occur until a qualified bat biologist has determined the young bats are no longer roosting and the breeding roost has dispersed from the structure or riparian and forested woodlands they are found in." Additionally, if presence is documented within structures that will be removed on the Centennial Industrial site or the Brunswick Industrial site, along with potential presence within the mine shaft, may result in potentially significant impacts that need to be analyzed and mitigated for accordingly and included in the DEIR. |
| Agcy 3-30 | | 10 | 4.4 | 4.4-73 | 470 | The DEIR does not discuss the potential for additional roosting habitat that may be created from the dewatering of the Idaho-Maryland Mine and the impacts that mining operations could potentially have on bats. | CDFW recommends the DEIR analyze the potential for the Project to impact bats, especially the on going mining activities within the Idaho-Maryland Mine should bats move into the mines once they are dewatered. If potentially significant impacts are identified, the DEIR should describe how the Project will avoid, minimize, and mitigate to a less than significant level. |
| Agcy 3-31 | | 11 | | | | The DEIR lists a number of mitigation measures for biological resources that rely on future approvals or agreements as a means to bring identified significant environmental effects to below a level of significance. | CEQA Guidelines §15126.4 (a)(1)(B) states that formulation of mitigation measures should not be deferred until some future time. Because there is no guarantee that these approvals or cooperation with all of the involved entities will ultimately occur, the mitigation measures are unenforceable and do not reduce the impacts to biological resources to a less than-significant level. CDFW recommends forming mitigation measures that are actionable and enforceable. |
| Agcy 3-32 | | 12 | 2 | 2-54 | 104 | Under mitigation measure 4.4-3(b) "Place staging areas and other work areas outside of the 50-foot non-disturbance buffers of ephemeral and intermittent aquatic resources and 100-foot nondisturbance buffers of perennial aquatic resources." Staging areas should be adequately distanced from sensitive resources. | Under F&G code 5652, CDFW recommends a 150 foot buffer from the high water mark for all staging areas to prevent unlawfully depositing or placing debris or waste where it can pass into the waters of the state. CDFW recommends including staging areas and other work areas in the Project's subsequent notification pursuant to Section 1602 of the Fish and Game Code to ensure their inclusion in any Lake and Streambed Alteration (LSA) Agreement that may be needed prior to commencing any activity that could deposit debris, waste or other materials where it may pass into any river, stream or lake. |
| Agcy 3-33 | | 13 | 2 | 2-56 | 106 | 4.4-3(c) "... Compensatory mitigation can include but is not limited to the following: onsite and/or offsite wetland creation and/or restoration, purchase or placement of conservation easements, payment of an in-lieu fee, and/or purchase of mitigation credits at an approved Corps wetland mitigation or conservation bank." | CDFW is not currently signatory to any in-lieu fee programs and therefore will not likely accept participation in these programs as compensatory mitigation for temporary or permanent loss of wetland habitat. Additionally, any credits purchased should be from a CDFW-approved mitigation or conservation bank to avoid needing to buy credits from multiple banks. CDFW recommends coordinating with all regulatory permitting agencies early and concurrently in the process to reduce the need to mitigate separately for each agency. |
| Agcy 3-34 | | 14 | 4.4 | 4.4-84 | 481 | In Figure 4-4.10 for the Brunswick Industrial Site, it shows the South Fork Wolf Creek flowing near the Water Treatment Pond and a wetland abutting the pond to the northwest. | Please identify how the treatment pond will be constructed to ensure high rain events will not result in untreated water passing into the abutting wetland or South Fork Wolf Creek. |
| Agcy 3-35 | | 15 | 4.4 | 4.4-20 | 417 | Table 4.4-5 has Pine Hill flannelbush (*Fremontodendron decumbens*) potential for presence on the Centennial Industrial Site as High. There have been multiple confirmed cases of presence on the Centennial Industrial Site from the 2019 Pine Hill flannelbush protocol-level surveys and on CNDDB. | CDFW recommends changing the potential status from 'high' to 'present' for the Centennial Industrial Site. |

Rancho Cordova, CA 95670

**Subject: Electrofishing Sample at South Fork Wolf Creek, Nevada County, March 8, 2022**

**Agcy 3-36**

In January of 2022, California Department of Fish and Wildlife (CDFW; Department) received a Notice of Availability of a Draft Environmental Impact Report (EIR) and Notice of Public Meeting to Provide Comments on the Idaho-Maryland Mine Draft EIR Project (https://www.mynevadacounty.com/3195/Idaho-Maryland-Mine---Rise-Grass-Valley). Upon review of the Draft EIR, Department staff found that potential impacts to the finfish of South Fork Wolf Creek were not addressed with the same rigor afforded other species of concern. Moreover, the Department did not have reliable and current information about the species of fish present in South Fork Wolf Creek. As a result, Department staff sampled South Fork Wolf Creek in three locations downstream of the proposed project to identify the species and life stages of finfish present in an effort to inform the Department's comments regarding the Draft EIR.

On March 8, 2022, CDFW Water Program Supervisor, Brianna Seapy, and two Environmental Scientists, Bridget Gibbons, and Mitch Lockhart, sampled South Fork Wolf Creek at three locations along East Bennet Road, Grass Valley, CA, (**Figure 1**) using a single Smith-Root backpack electrofisher. Mitch Lockhart selected sites that were downstream of the project, accessible via public land, and representative of South Fork Wolf Creek's diversity of instream habitats. The Smith-Root backpack electrofisher was set at 30 hertz, 20% duty cycle, and 350 volts. All fish captured were identified to species, measured to the nearest millimeter, and released near the point of capture.

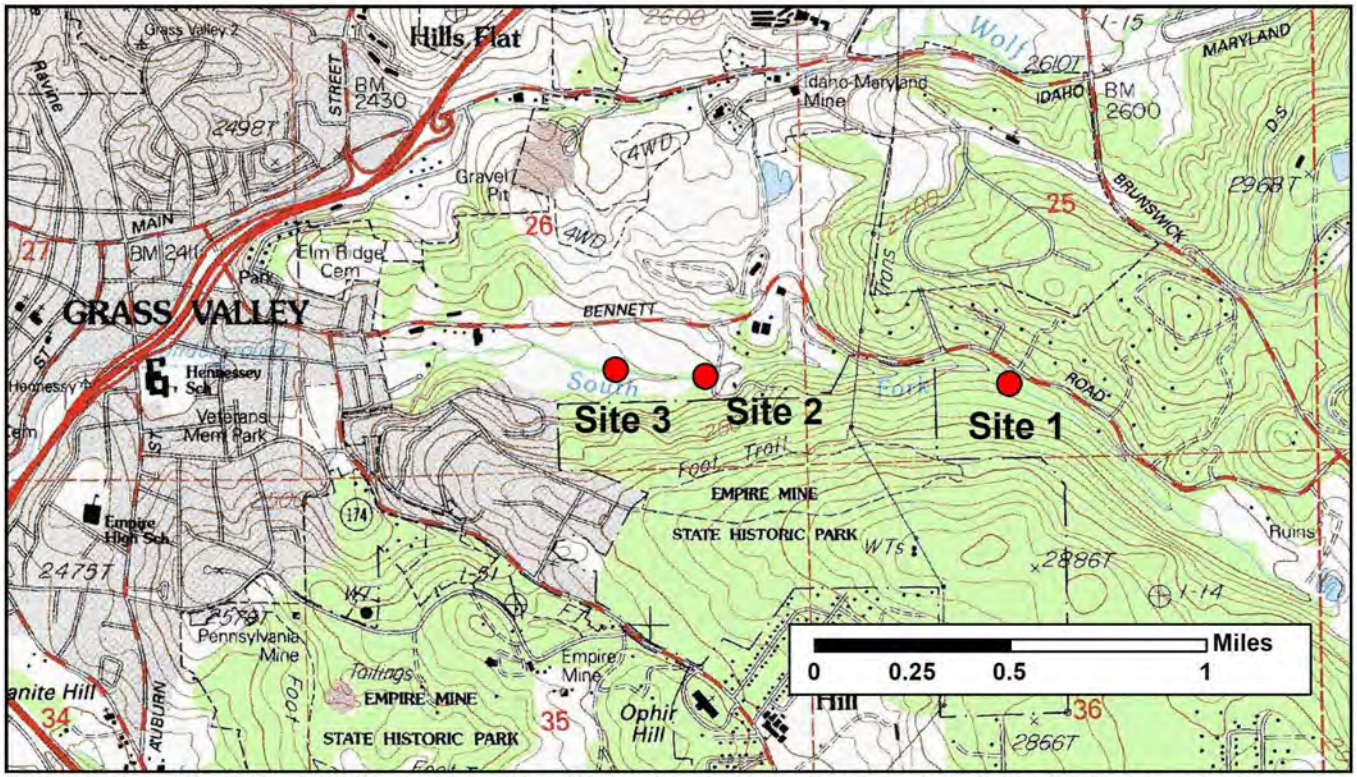

***Figure 1:*** *Map of South Fork Wolf Creek, Grass Valley, Nevada County. Red dots denote electrofishing locations sampled by Department staff on March 8, 2022.*

**Table 1: Fish data from South Fork Wolf Creek, March 8, 2022.**

| Site | Species | Total Length (mm) | Total Length (inch) |
|---|---|---|---|
| Site 1 | Brown Trout | 129 | 5.1 |
| Site 1 | Brown Trout | 143 | 5.6 |
| Site 1 | Brown Trout | 145 | 5.7 |
| Site 2 | Bluegill | 52 | 2.0 |
| Site 2 | Bluegill | 100 | 3.9 |
| Site 2 | Brown Trout | 86 | 3.4 |
| Site 2 | Brown Trout | 93 | 3.7 |
| Site 2 | Brown Trout | 95 | 3.7 |
| Site 2 | Brown Trout | 98 | 3.9 |
| Site 2 | Brown Trout | 100 | 3.9 |
| Site 2 | Brown Trout | 104 | 4.1 |
| Site 2 | Brown Trout | 107 | 4.2 |
| Site 2 | Brown Trout | 114 | 4.5 |
| Site 2 | Brown Trout | 144 | 5.7 |
| Site 2 | Brown Trout | 171 | 6.7 |
| Site 2 | Brown Trout | 195 | 7.7 |
| Site 2 | Brown Trout | 230 | 9.1 |
| Site 3 | Bluegill | 98 | 3.9 |
| Site 3 | Brown Trout | 105 | 4.1 |
| Site 3 | Brown Trout | 109 | 4.3 |

The sampling data are summarized in **Table 1**. Site 1 is a step pool system characterized by bedrock substrate and significant woody debris. Gravel and cobble substrates are limited to pool tails and small riffles between steps. Department staff captured three Brown Trout (*Salmo trutta*). Fish captured in Site 1 had damaged and worn caudal and dorsal fins and were of poor body condition (**Figure 2**). Fish were thinly distributed, only occupying the most oxygenated step pools with plenty of unoccupied habitat between fish occurrences. These preliminary data suggest that Brown Trout migrate into this site from more ideal spawning and rearing habitats downstream.

Site 2 is a well-oxygenated riffle over cobble and gravel substrate, with well-covered, slow-moving, holding habitats. Department staff captured twelve BN and two Bluegill (*Lepomis macrochirus*). Fish captured in Site 2 were of good body condition with healthy fins and no visible signs of disease (**Figure 2**). Site 2 had the highest fish density and diversity of Brown Trout sizes suggesting that Site 2 is a spawning and rearing location for Brown Trout.

Site 3 is a slow-moving set of two deep pools characterized by silt substrate and woody debris. Department staff captured two Brown Trout and one Bluegill. The pools provide ideal holding habitat, but do not offer any gravel substrate for spawning, nor any source of oxygenated water. Fish captured in Site 3 were of good body condition with healthy fins and no visible signs of disease. The pools were too deep to sample effectively with a single backpack electrofisher. As a result, fish density may have been higher at Site 3 then the data reflect.

**Agcy 3-37**

These preliminary data clearly indicate South Fork Wolf Creek supports a wild and self-sustaining population of Brown Trout and non-native sunfish. Further surveys are necessary to estimate the size of the Brown Trout population, and to delineate habitats critical to Brown Trout reproduction and rearing.

***Figure 2:*** *Photos of two Brown Trout (Salmo trutta) captured from South Fork Wolf Creek, Grass Valley, Nevada County, by backpack electrofisher on March 8, 2020. The left panel is a Brown Trout with poor body condition captured in Site 1 and can be contrasted against the Brown Trout in the right panel with good body condition captured in Site 2.*

## AGENCY LETTER 3: SHAUNDRA CASHDOLLAR, CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE

### Response to Comment Agcy 3-1
Comment noted. This is an introductory statement regarding CDFW's role as a responsible agency and does not provide a comment regarding the adequacy of the DEIR.

### Response to Comment Agcy 3-2
Comment noted. This is an introductory comment summarizing CDFW's understanding of the project and does not provide a comment regarding the adequacy of the DEIR.

### Response to Comment Agcy 3-3
This is an introductory comment broadly outlining concerns detailed in the comment letter. Please see the following master responses addressing these issues:

- Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog;
- Master Response 36 - Flows in South Wolf Creek;
- Master Response 32 -Temperature of Mine Water Discharge;
- Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts;
- Master Response 34 - Resident Fish;
- Master Response 37 - Birds and Raptors; and
- Master Response 31 - Rare Plants.

### Response to Comment Agcy 3-4
This comment provides general information regarding the requirements of the Native Plant Protection Act and refers to comment Agcy 3-7.

### Response to Comment Agcy 3-5
Comment noted. Mitigation Measure 4.4-1(b) outlines the requirements for preparation of a County required Habitat Management Plan if special-status plant species are identified onsite. The County Habitat Management Plan is not intended to supersede state and/or federal take requirements associated with any special-status species. The applicant would obtain approval of an ITP, as necessary, for take of any California-listed special-status species. In order to provide this clarification, Mitigation Measure 4.4-1(a), on page 4.4-64 of the DEIR, has been revised in this Final EIR. Please see Response to Comment Grp 12-34.

Additionally, the third paragraph of Mitigation Measure 4.4-1(b) has been revised to read as follows:

> *If any special-status plant species are found, ~~protection of such plant shall include complete avoidance, transplantation, or on- or off-site restoration of the special-status plant species that could be impacted by site disturbance. These protective measures for such plants shall be included as part of the required development of a Habitat Management Plan (HMP) as part of compliance with the Nevada County Land Use and Development Code, Section L-II 4.3.12, which includes regulations intended to avoid the impact of development on rare, threatened, endangered, and special-status species and their habitat, or where avoidance is not possible, to minimize or compensate for such impacts and to retain their habitat as non-disturbance open space.~~ and they are located in an area where impacts are proposed, then the special-status plants shall be completely avoided until a Habitat Management Plan*

> *(HMP) is developed and approved by the Nevada County Planning Department. If the plant is listed on the federal or state Endangered Species lists or is state listed as rare, then development of this plan shall be conducted in consultation with USFWS and/or CDFW, respectively, and a BO and/or an ITP shall be obtained prior to impacts. The HMP shall include the avoidance, minimization, and mitigation measures outlined below as part of compliance with the Nevada County Land Use and Development Code, Section L-II 4.3.12. Note that transplantation and monitoring specifics are examples only, and final details will be developed based on the species to be impacted, if any.*

The changes to Mitigation Measures 4.4-1(a) and (b) are provided for clarification purposes in Response to Comment Agcy 3-5 and do not affect the adequacy of the analysis contained in the DEIR, nor alter the conclusions therein.

## Response to Comment Agcy 3-6

The commenter states that the project should include a variety of mitigation strategies, including conservation, preservation, restoration, habitat enhancement, and avoidance. Restoration is included as a major aspect of the mitigation for impacts to this species as outlined in Mitigation Measure 4.4-1. The DEIR includes a variety of mitigation measures depending on the potential impacts, local, state or federal permitting requirements, and specifics of that particular species. For example, Mitigation Measure 4.4-1(a) for the Pine Hill flannelbush includes transplant and seed collection measures (if feasible), habitat enhancement, and conservation easement in order to mitigate project impacts. Impact 4.4-2, analyzing project impacts to special-status species, includes mitigation measures requiring preconstruction surveys and preparation of County required management plans. In addition, depending on the species, if identified onsite, consultation with the appropriate state or federal agency may be required. Finally, impacts to waters and wetlands in Impact 4.4-3 are mitigated through subsequent permitting with various state and federal agencies. As demonstrated, a variety of mitigation measures, many with numerous steps and tiered requirements depending on the specie or survey results, will be implemented to reduce project biological impacts to a less than significant level.

## Response to Comment Agcy 3-7

This comment provides general information on the Incidental Take Permit requirements in the event project activities require application for and issuance by CDFW. The DEIR Mitigation Measures for state-listed wildlife species already require approval of an ITP, as necessary for take of any California-listed special status species. As shown in Response to Comment Agcy 3-5, the Final EIR mitigation measures for plants have been revised to require approval of an ITP for state-listed plant species.

## Response to Comment Agcy 3-8

Please see Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog.

## Response to Comment Agcy 3-9

Comment noted. For clarification purposes, Table 4.4-6 of the DEIR has been revised accordingly:

| | |
|---|---|
| **Foothill yellow-legged frog**<br>*Rana boylii* | SCT/S<u>T</u>~~CC~~ |

The above minor change is for clarification purposes and does not affect the analysis, nor conclusions, in the DEIR.

## Response to Comment Agcy 3-10

A callback survey is not considered a "take" under Fish and Game Code Section 86 based on the plain language of the Fish and Game Code and the legal authorities interpreting the definition of "take" under state and federal laws. Fish and Game Code Section 86 states that "'Take' means hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." A prerequisite for a take to occur under CESA (Fish & Game Code § 2050 et seq.) is that an act actually kills or injures wildlife. (78 Ops. Cal. Atty. Gen. 137 at p. *3 (May 15, 1995).) Callback surveys are not listed in, and do not involve activities that would meet, the definition of "take" in Fish and Game Code Section 86. In addition, the callback survey is implemented for the detection of a species, and does not involve the killing or injuring of animals, therefore is not considered take. The DEIR has analyzed project-specific impacts to special-status species and their habitats in DEIR Chapter 4.4 and recommended mitigation measures where a potential impact was identified. Many of these mitigation measures recommended avoidance where feasible. Note that California Black Rail was considered to have a "very low" likelihood of being found onsite in the DEIR. If California Black Rail is found onsite, the applicant will consult with CDFW to avoid take of this species. Note that the DEIR reflected that California Black Rail is California Threatened, but it is also considered California Fully Protected. The DEIR has been amended to reflect the Fully Protected status for this species. Additionally, Mitigation Measure 4.4-2(d) has been amended to remove reference to an ITP being obtained for take of California Black Rail. As this species is considered to have a very low potential to be found onsite, surveys will be conducted prior to site disturbance, and consultation with CDFW and avoidance shall be required in the case of species presence; this impact is still considered less than significant.

The following clarifications to Chapter 4.4, Biological Resources, of the DEIR are hereby implemented in response to the comment:

Table 4.4-6 is hereby revised as follows:

| | |
|---|---|
| **California black rail**<br>*Laterallus jamaicensis coturiculus* | --/CT<br>California Fully Protected |

Page 4.4-39 (description of California black rail) is hereby revised as follows:

> California black rail (*Laterallus jamaicensis coturiculus*) – CA State Threatened and CA State Fully Protected
>
> California black rail inhabits freshwater marshes, wet meadows and shallow margins of saltwater marshes bordering larger bays. The species requires water depths of approximately one inch that does not fluctuate during the year and dense vegetation for nesting habitat.

Mitigation Measure 4.4-2(d), pertaining to California black rail, is hereby revised as follows:

> *California Black Rail*
>
> *4.4-2(d) Pre-construction Survey and Avoidance and Minimization Measures. Pre-construction surveys for California black rail shall be conducted by a qualified biologist prior to the implementation of any ground disturbance within or directly adjacent to any perennial marsh and wet meadow habitat within the Centennial and Brunswick Industrial Sites. The pre-construction surveys for this species shall occur no more than fourteen (14) days prior to any such disturbance within or directly adjacent to the species habitat. The pre-construction surveys shall include conducting call back/response surveys. This species is most active between two*

*hours before and three hours after sunrise; therefore, surveys shall start at sunrise and continue no later than 0930. If evening surveys are to be conducted, they shall be paired with a morning survey, and all sites shall have surveys conducted at both time periods. The preferred method for conducting surveys via the call-back/response protocol of Evens et al (1991). If the pre-construction survey does not detect evidence of California black rail, a letter report documenting the results of the survey shall be provided to the Nevada County Planning Department, and additional measures are not required. If a positive call back is identified during the surveys, then the species is assumed to be present and the area shall be avoided from disturbance in order to avoid impacts to individuals of the species, if feasible.*

*Given the species is a CESA listed species, coordination with CDFW shall occur if a positive response to the call-back/response surveys occurs and if any proposed disturbance may impact the species. Any area containing this species would likely need to be avoided in order to avoid impacts to and take of this species, if feasible, or additional mitigation measures would be required in coordination with CDFW to minimize and avoid impacts to such species. Additional avoidance measures could include, but may not be limited to the following: environmental awareness training, daily construction monitoring by a CDFW qualified biologist when disturbance related activities occur within or directly adjacent to the species habitat, and exclusionary fencing installation between the species habitat and the proposed disturbance areas. ~~Additionally, an ITP could be required by CDFW if complete avoidance of the species is not feasible.~~ Areas where no positive response to the call-back/response surveys are assumed to not contain individuals of the species and therefore, disturbance in those areas would have no impact on this species.*

*Watercourse/Wetlands/Riparian Areas Management Plans. The applicant shall implement the mitigation measures identified in the Aquatic Resources Management Plans for the Centennial and Brunswick Industrial Sites, pursuant to Mitigation Measure 4.4-3, which include measures designed to protect aquatic resources and the biological resources they support. Such measures generally include, but are not limited to, mitigation for encroachment into non-disturbance buffers, restoration of impacted areas within stream zones, implementation of BMPs during construction, and post construction erosion control.*

The above minor changes are for clarification purposes and do not affect the analysis, nor conclusions, in the DEIR regarding California black rail.

## Response to Comment Agcy 3-11

The commentor generally notes not all potential impacts to aquatic features were analyzed but does not specifically provide what impacts were not analyzed. DEIR Chapter 4.4, analyzed potential biological impacts including impacts to aquatics features and associated habitat. This impact analysis was based on eleven different technical studies prepared by experts in their fields, and followed up by a County peer review using a independent biology firm. Technical studies specifically included aquatic resources determinations for both the Centennial and Brunswick Industrial sites and draft County management plans for potential impacts to watercourses/wetlands/riparian areas. DEIR Impact 4.4-3 analyzed the project's potential to impact state or federally protected waters and wetlands and determined this impact was potentially significant. Mitigation measures 4.4-3(a-d) were identified that reduce this impact to a less than significant level. Mitigation Measure 4.4-3(d) specifically requires the applicant to apply for a CDFW 1600 Streambed Alteration Agreement. The impact analysis and mitigation measures comprehensively address potential project impacts to waters and wetlands on the project site.

Please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts.

## Response to Comment Agcy 3-12

The commenter asserts that the DEIR should provide further analysis of impacts and mitigation for impacts to Brown Trout found in South Fork Wolf Creek; however, Brown Trout are an invasive species, and even if they were not an invasive species, there is no evidence provided by commenter that any impact will occur. Please see Master Response 34 - Resident Fish. Furthermore, CEQA does not require an analysis of impacts to all resident fish, but only to those considered special-status pursuant to CEQA guidelines. The only fish that have been documented in Wolf Creek and South Fork Wolf Creek are non-native fish (brown trout and bluegill). As such, no analysis of impacts to "resident fish" is appropriate under CEQA.

## Response to Comment Agcy 3-13

The DEIR does include a discussion of potential impacts of lowering the groundwater table on vegetation in the context of wildfire (see page 4.13-21). Please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts.

Please also see Master 33 - Groundwater Dependent Vegetation, regarding potential groundwater drawdown impacts to surface vegetation. Further, in order to clarify that groundwater drawdown induced from the mine would not impact groundwater dependent (phreatophytic) vegetation, Itasca Denver prepared a memo showing the simulated drawdown in selected meadows. These three meadows (Brunswick site, Empire Mine Park, and Loma Rica) would experience minimal drawdown, even without consideration of the minewater discharge to South Fork Wolf Creek. The Empire Park Meadow would experience no drawdown with the addition of 1.9 cfs (average maintenance dewatering rate) and less than 1 inch of drawdown with no added flow from mine dewatering. (See Itasca Memo – Simulated Drawdown of Selected Meadows attached to the Final EIR as Appendix H). If the addition of mine water discharge were considered, there would likely be even less impact. As such, this impact to groundwater dependent vegetation is still considered less than significant.

## Response to Comment Agcy 3-14

Please see Master Response 32 - Temperature of Mine Water Discharge, regarding the temperature of treated water discharge into South Wolf Creek.

As discussed on page 4.8-66 of the DEIR, the total flow reduction in base flow to Wolf Creek from the project is minimal and barely perceptible compared to the existing base flow. Furthermore, Wolf Creek will be considered a COLD water body for the application of water quality objectives. The water currently draining from the mine (0.13 to 0.28 cfs) is warmer than Wolf Creek during all seasons (See Table 3-5 and 3.8 of Appendix K.2). Therefore, elimination of the drainage will not increase water temperature in Wolf Creek. The base flow of Wolf Creek would be reduced by 0.75 cfs due to reduction in groundwater discharge to the creek. This groundwater would be warmer than surface water during winter months and cooler in summer months. During the summer months, high flows are present in Wolf Creek (approximately 40 cfs). Any potential loss of cooling from groundwater would be minimal as the observed baseflow in Wolf Creek at the Centennial Drive bridge ranges from about 40 to 100 times greater than the projected decrease of 0.75 cfs. In addition, please see Master Response 36 - Flows in South Fork Wolf Creek and Wolf Creek.

## Response to Comment Agcy 3-15

The commenter states that the DEIR should analyze the cumulative impacts of the project's proposed hydrological changes on ecosystems. The DEIR already analyzed the project's cumulative impacts on biological resources and concluded that the project could have a cumulatively considerable impact, absent mitigation. (DEIR, p. 4.4-96.) The DEIR then concludes that after implementation of Mitigation Measures 4.4-1(a-b), 4.4-2(a-g), and 4.4-3(a-d), the project's incremental contribution to cumulative biological resources impacts would be reduced to a less than cumulatively considerable level.

The DEIR has already concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measure 4.8-1(a) to address these potential impacts. This mitigation measure requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. The NOI shall include evaluation of potential constituents of concern and demonstrate that water treatment plant (WTP) design shall successfully treat mine water to meet the water quality standards and treatment goals.

As stated on Page 11 of NPDES CAG995002 ORDER R5-2022-0006, the requirements of the Order are specifically drafted to implement the Basin Plan's policies and objectives. The Basin Plan considers all beneficial uses including environmental uses. (See Response to Comment Agcy 3-16).

The mitigation measure therefore ensures the protection of beneficial uses. This includes the preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates (COLD). This includes uses of water that support terrestrial or wetland ecosystems including, but not limited to, preservation and enhancement of terrestrial habitats or wetlands, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), or wildlife water and food sources (WILD).

As discussed in Master Response 32 - Temperature of Mine Water Discharge, Master Response 33 - Groundwater Dependent Vegetation, Master Response 34 - Resident Fish, Master Response 35 - Discharge to South Fork Wolf Creek, and Master Response 36 - Flows in South Fork Wolf Creek, the project's impacts on the ecosystem and riparian habitats due to groundwater drawdown and the discharge into South Fork Wolf Creek will not be significant, and may be beneficial for some species due to the increased flows of approximately 1.9 to 5.6 cfs of clean water that meets CVRWQCB standards. Likewise, impacts to groundwater dependent vegetation are shown to be very small (e.g., only an inch of drawdown in the Empire Park Meadow, without even considering the additional recharge from increased flows) and are therefore expected to be less than significant. With regard to the commenter's question on the closure of the mine and the return to baseline conditions, it is expected that refilling of the mine will only take a few years (1 to 2 years), and therefore will quickly return to pre-project conditions without any long-term effect. As stated on page 4.8-51 of the DEIR, once mining is completed, dewatering ceases, and the underground workings are allowed to flood with groundwater, the same reducing conditions that occur under existing conditions within the mine workings would develop again, preventing oxidation of sulfide minerals. Water quality in the re-flooded mine workings would then have the same general pH, TDS, and other water quality conditions that occur under existing conditions. The underground workings are anticipated to refill over the next several years (1 to 2 years). Thus, any seepage from drains and fractures within the bedrock would have a comparable water quality to the discharge from the drains along Wolf Creek under existing conditions. During the refilling of the mine, the drawdown impacts from dewatering will gradually return to pre-project conditions while the increased flow conditions in South Fork Wolf Creek will cease. This refilling period will

not cause an impact as it will represent a return to pre-project baseline conditions and is temporary.

The project itself will not cause a significant impact to the ecosystem due to changed hydrology, and the project combined with the cumulative list of projects is not expected to cause a cumulatively considerable impact to the environmental users of groundwater, habitats or aquatic resources during the life of the project.

## Response to Comment Agcy 3-16

Please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts. Given that the project will not significantly impact beneficial uses to South Fork Wolf Creek, as discussed in the abovementioned Master Responses, the project's much smaller contribution to overall flow in Wolf Creek, as compared to South Fork Wolf Creek, is also not expected to impact beneficial uses in Wolf Creek.

The Regional Water Board adopted a Water Quality Control Plan, Fifth Edition, for the Sacramento and San Joaquin River Basins (hereinafter "Basin Plan") that designates beneficial uses, establishes water quality objectives, and contains implementation programs and policies to achieve those objectives for all waters addressed through the Basin Plan. The Basin Plan at page 2.3 states that the "…beneficial uses of any specifically identified water body generally apply to its tributary streams." The Basin Plan does not specifically identify beneficial uses for South Fork of Wolf Creek but does identify present and potential uses for the Bear River, to which the South Fork of Wolf Creek and Wolf Creek are tributary. As discussed on page 4.8-31 of the DEIR, the beneficial uses of Bear River and South Fork Wolf Creek are identical and therefore the potential downstream impacts to the Bear River are already analyzed in the DEIR.

As discussed on page 15 of Appendix K.2, much of the flow within Wolf Creek is due to releases of water by Nevada Irrigation District (NID). In 2018, the releases to Wolf Creek averaged approximately 36 cfs. On April 17, 2019, EMKO measured the flow in Wolf Creek at the Centennial Drive bridge (at the intersection with Idaho-Maryland Road) at approximately 50 cfs. EMKO also measured the flow in Wolf Creek at the Centennial Drive bridge on August 8, 2019. At that time, the flow was estimated to be approximately 75 cfs. The flow of the Bear River is not discussed in the DEIR. However, a USGS gage station is located on the Bear River downstream of Rollins Reservoir (USGS Station 11422500, Bear River below Rollins Reservoir, Near Colfax). Mean water flow in the Bear River at this station ranges from approximately 110 cfs to 1,000 cfs over the previous 10 water years.

https://waterdata.usgs.gov/nwis/annual?referred_module=sw&site_no=11422500&por_11422500_216838=2209688,00060,216838,1912,2021&year_type=W&format=html_table&date_format=YYYY-MM-DD&rdb_compression=file&submitted_form=parameter_selection_list

## Response to Comment Agcy 3-17

Comment noted. Responses to Attachment 1 are provided in Responses to Comments Agcy 3-21 through 3-37.

## Response to Comment Agcy 3-18

The comment does not provide a comment regarding the adequacy of the DEIR. Comment noted.

## Response to Comment Agcy 3-19

The comment does not provide a comment regarding the adequacy of the DEIR. Comment noted.

## Response to Comment Agcy 3-20

The comment does not provide a comment regarding the adequacy of the DEIR. Comment noted. The County will continue to provide CDFW with project notifications.

## Response to Comment Agcy 3-21

A list of potential permits and approvals is provided in DEIR section 3.8, Requested Discretionary Actions.

## Response to Comment Agcy 3-22

Draft management plans detailing potential disturbance within the 100-foot setback from riparian areas were provided in Appendix F.5, F.8, and K.6 to the DEIR.

## Response to Comment Agcy 3-23

Please see Appendix F.4 detailing seed collection techniques for the Pine Hill Flannelbush, including information on how many seeds will be collected as requested by the commenter. As stated on page 6-2 of Appendix F.4, approximately 30-100 seeds per plant were collected from four plants in 2019 and are stored in the seedbank of UC Santa Cruz. Additional seeds will be collected to have enough seed and it is recommended that up to 400 seeds should be collected from each plant to be destroyed or planted to have sufficient buffers for future propagation efforts and for seed banking.

## Response to Comment Agcy 3-24

In response to the comment, Mitigation Measure 4.4-1(b), paragraph four, fifth bullet, is hereby revised as follows:

> *At a minimum, the HMP shall include the following protective measures for special-status plant species with the potential to be impacted by the proposed disturbance:*
>
> - *a map of the location of special-status species that may be disturbed or need to be protected;*
> - *location of environmental protection fencing to be placed around the individual plants to be protected;*
> - *identification of the location of protected plants on design and construction drawings;*
> - *environmental awareness training for all personnel working on the project during initial site disturbance to discuss the location of the protected plants and the measures to be taken to avoid impacts to them; and*
> - *a qualified biologist shall be onsite during all vegetation and ground disturbing activities that are within the vicinity of special-status plants and weekly ~~site~~ monitoring of the protective fencing along fencing along the buffer zone~~by a qualified biologist to ensure that the special-status plants are being protected during site disturbance and construction~~.*

The above minor revisions are made in response to the comment and do not affect the adequacy of the analysis, nor the conclusions in the DEIR.

## Response to Comment Agcy 3-25

As detailed in DEIR Impact 4.4-1, other than Pine Hill flannelbush, no other List 1 or 2 plant species were identified onsite during rare plant surveys. It would be premature at this time to identify specific measures for potential rare plants to occur. As detailed in Mitigation Measure 4.4-1(b), if List 1 or 2 rare plants are identified during follow-up surveys, a management plan will be prepared consistent with Nevada County Land Use and Development Code, Section L-II 4.3.12.

## Response to Comment Agcy 3-26

Mitigation measure 4.4-2(b) states the qualified biologist shall have a CDFW handling permit.

## Response to Comment Agcy 3-27

Mitigation Measure 4.4-2(e) has been clarified per the commenter's suggestion, as follows:

> *Coast Horned Lizard*
>
> *4.4-2(e)* *Pre-construction Survey and Avoidance and Minimization Measures. A pre-construction survey shall be conducted by a qualified biologist no more than seven (7) days prior to disturbance within the areas of the Centennial and Brunswick Industrial Sites that contain disturbed or developed surfaces and annual grassland vegetation community. If the pre-construction survey does not show evidence of coast horned lizard, a letter report documenting the results of the survey shall be provided to the Nevada County Planning Department, and additional measures are not required.*
>
> *If the species is documented during pre-construction survey(s), a qualified wildlife biologist (approved by CDFW) shall move individual coast horned lizards outside of the proposed disturbance area(s) in order to avoid an impact to this species. The qualified biologist shall have all required permits before commencing species specific surveys. Once the coast horned lizard(s) have been removed from the disturbance area(s) and out of harm's way, the proposed work would no longer pose a risk to individuals of the species.*

The above minor revision is made in response to the comment and does not affect the adequacy of the analysis, nor the conclusions in the DEIR.

## Response to Comment Agcy 3-28

The commenter provides recommendations for timing of pre-construction bat surveys required in Mitigation Measure 4.4-2(f) of the DEIR. The comment will be considered by the qualified biologist during implementation of said mitigation. Comment noted.

## Response to Comment Agcy 3-29

Mitigation Measure 4.4-2(f) has been clarified per the commenter's suggestion, as shown below. The Brunswick shaft is currently sealed with a steel cover and no special species bats are present in the mine shaft. As discussed on page 4.4-73 of the DEIR, the potential for species to occur at the Brunswick Area is considered low. The migration to, and presence of, special species bats in the future dewatered and operating underground mine and constructed headframes is speculative and CEQA does not require that an EIR analyze speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence."

Mitigation Measure 4.4-2(f) is hereby revised as follows:

*Special-Status Bats*

*4.4-2(f)* *Pre-construction Survey and Avoidance and Minimization Measures. A pre-construction bat roosting survey shall be conducted by a qualified biologist no more than seven (7) days prior to disturbance of any structures or riparian and forested woodlands within the Centennial Industrial Site and Brunswick Area to identify the presence or absence of roosting bats. If the pre-construction survey does not show evidence of roosting bats, a letter report documenting the results of the survey shall be provided to the Nevada County Planning Department, and additional measures are not required.*

*If any Townsend's big-eared bats (or any other species of bat, including the hoary and pallid bat) are identified during roosting surveys, passive removal of the roosting bats prior to disturbance to structures and riparian and forested woodlands shall be implemented to avoid impacts to this species. Passive removal includes allowing roosting bats to freely leave the roost site (riparian and forested woodlands and any structure). Once the roosting bats have been passively removed from the structure(s) and riparian and forested woodlands, the structure(s) would be closed off from recurring bat roosting within the structure(s) and the proposed work within the structure(s) would no longer pose a risk to individuals of the species. For riparian and forested woodlands containing bat roosts, the removal of trees associated with such woodlands would only occur once the bats leave the day roosts. Furthermore, if a maternal (breeding) roost is documented, no disturbance shall occur until a qualified bat biologist has determined the young bats are no longer roosting and the breeding roost has dispersed from the structure or riparian and forested woodlands they are found in.*

The above minor revision is made in response to the comment and does not affect the adequacy of the analysis, nor the conclusions in the DEIR.

## Response to Comment Agcy 3-30

As discussed on page 4.4-73 of the DEIR, the potential for species to occur at the Brunswick Area is considered low. The migration to, and presence of, special species bats in the future dewatered and operating underground mine and constructed headframe is speculative and CEQA does not require that an EIR analyze speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence."

## Response to Comment Agcy 3-31

Commenter states generally that the mitigation measures may constitute deferred mitigation but does not provide any specific examples. In this case, the provided mitigation has clear, enforceable performance standards and is not deferred mitigation. Compliance with a regulatory permit or other similar process may be identified as mitigation if compliance would result in implementation of measures that would be reasonably expected, based on substantial evidence in the record, to reduce the significant impact to the specified performance standards (CEQA Guidelines Section 15126.4.) In the case *Center for Biological Diversity v. California Department of Conservation, etc*. (2019), the court explains that "[g]enerally, it is improper to defer the formulation of mitigation measures…However, an exception to this general rule applies when the agency has committed itself to specific performance criteria for evaluating the efficacy of the

measures to be implemented in the future, and the future mitigation measures are formulated and operational before the project activity that they regulate begins." (36 Cal.App.5th 210, 239.) The court determined both conditions were met and upheld the deferred mitigation measures. Similarly, the mitigation measures presented in the DEIR require compliance with specific performance standards and regulatory requirements, and also require implementation prior to project activities begin.

## Response to Comment Agcy 3-32

The commenter recommends a 150ft buffer from perennial streams for placement of staging areas, based on Fish and Game Code Section 5652. However, Fish and Game Code Section 5652 states that it is "unlawful to deposit, permit to pass into, or place where it can pass into the waters of the state, or to abandon, dispose of, or throw away, within 150 feet of the high water mark of the waters of the state, any cans, bottles, garbage, motor vehicle or parts thereof, rubbish, litter, refuse, waste, debris, or the viscera or carcass of any dead mammal, or the carcass of any dead bird." The project does not propose to dispose of any of the listed items into the stream or to dispose of any such item within 150 feet of the stream. Rather, a staging area may be placed no closer than 100 feet from the perennial stream, and items would not be disposed of within 150 feet of the high water mark of the stream, in compliance with the cited Fish and Game Code Section 5562. The applicant is required to comply with California Fish and Game Code Section 5652, regardless of the mitigation measure's buffer size. The comment is noted.

## Response to Comment 3-33

The comment is noted and will be considered by the qualified biologist and applicant during mitigation compliance.

## Response to Comment Agcy 3-34

The water treatment pond is an existing site feature with a 40-acre foot capacity. Please see DEIR Impact 4.8-3 analyzing the capacity of the water treatment pond and determining sufficient capacity exists based on the storm events modelled. Please also see Appendix K.5 detailing Brunswick Industrial Site drainage and stormwater facility sizing.

## Response to Comment Agcy 3-35

Table 4.4-5 of Chapter 4.4 has been updated per the commenter's suggestion, as shown on the following page. The minor change is for clarification purposes and does not alter the analysis, nor conclusions, within the DEIR.

## Response to Comment Agcy 3-36

Comment noted. Please see Master Response 34 - Resident Fish.

## Response to Comment Agcy 3-37

Comment noted. Please see Master Response 34 - Resident Fish.

**Agency Letter 4**

Central Valley Regional Water Quality Control Board

9 March 2022

Matt Kelley
Nevada County Planning Department
950 Maidu Avenue, Suite 170
Nevada City, CA 95959-8617
*Idaho.MMEIR@co.nevada.ca.us*

**COMMENTS TO REQUEST FOR REVIEW FOR THE DRAFT ENVIRONMENTAL IMPACT REPORT, IDAHO-MARYLAND MINE PROJECT, SCH#2020070378, NEVADA COUNTY**

**Agcy 4-1**

Pursuant to the State Clearinghouse's 3 January 2022 request, the Central Valley Regional Water Quality Control Board (Central Valley Water Board) has reviewed the *Request for Review for the Draft Environmental Impact Report* for the Idaho-Maryland Mine Project, located in Nevada County.

Our agency is delegated with the responsibility of protecting the quality of surface and groundwaters of the state; therefore our comments will address concerns surrounding those issues.

**I. Regulatory Setting**

**Basin Plan**

**Agcy 4-2**

The Central Valley Water Board is required to formulate and adopt Basin Plans for all areas within the Central Valley region under Section 13240 of the Porter-Cologne Water Quality Control Act. Each Basin Plan must contain water quality objectives to ensure the reasonable protection of beneficial uses, as well as a program of implementation for achieving water quality objectives with the Basin Plans. Federal regulations require each state to adopt water quality standards to protect the public health or welfare, enhance the quality of water and serve the purposes of the Clean Water Act. In California, the beneficial uses, water quality objectives, and the Antidegradation Policy are the State's water quality standards. Water quality standards are also contained in the National Toxics Rule, 40 CFR Section 131.36, and the California Toxics Rule, 40 CFR Section 131.38.

The Basin Plan is subject to modification as necessary, considering applicable laws, policies, technologies, water quality conditions and priorities. The original Basin Plans were adopted in 1975, and have been updated and revised periodically as required, using Basin Plan amendments. Once the Central Valley Water Board has adopted a Basin Plan amendment in noticed public hearings, it must be approved by the State Water Resources Control Board (State Water Board), Office of

Administrative Law (OAL) and in some cases, the United States Environmental Protection Agency (USEPA). Basin Plan amendments only become effective after they have been approved by the OAL and in some cases, the USEPA. Every three (3) years, a review of the Basin Plan is completed that assesses the appropriateness of existing standards and evaluates and prioritizes Basin Planning issues. For more information on the *Water Quality Control Plan for the Sacramento and San Joaquin River Basins*, please visit our website:
http://www.waterboards.ca.gov/centralvalley/water_issues/basin_plans/

**Antidegradation Considerations**
All wastewater discharges must comply with the Antidegradation Policy (State Water Board Resolution 68-16) and the Antidegradation Implementation Policy contained in the Basin Plan. The Antidegradation Implementation Policy is available on page 74 at:
https://www.waterboards.ca.gov/centralvalley/water_issues/basin_plans/sacsjr_201805.pdf

In part it states:

*Any discharge of waste to high quality waters must apply best practicable treatment or control not only to prevent a condition of pollution or nuisance from occurring, but also to maintain the highest water quality possible consistent with the maximum benefit to the people of the State.*

*This information must be presented as an analysis of the impacts and potential impacts of the discharge on water quality, as measured by background concentrations and applicable water quality objectives.*

The antidegradation analysis is a mandatory element in the National Pollutant Discharge Elimination System and land discharge Waste Discharge Requirements (WDRs) permitting processes. The environmental review document should evaluate potential impacts to both surface and groundwater quality.

**II. Permitting Requirements**

**Construction Storm Water General Permit**
Dischargers whose project disturb one or more acres of soil or where projects disturb less than one acre but are part of a larger common plan of development that in total disturbs one or more acres, are required to obtain coverage under the General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities (Construction General Permit), Construction General Permit Order No. 2009-0009-DWQ. Construction activity subject to this permit includes clearing, grading, grubbing, disturbances to the ground, such as stockpiling, or excavation, but does not include regular maintenance activities performed to restore the original line, grade, or capacity of the facility. The Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). For more information on the Construction General Permit, visit the State Water Resources Control Board website at:
http://www.waterboards.ca.gov/water_issues/programs/stormwater/constpermits.shtml

Agcy 4-3

**Phase I and II Municipal Separate Storm Sewer System (MS4) Permits**[1]
The Phase I and II MS4 permits require the Permittees reduce pollutants and runoff flows from new development and redevelopment using Best Management Practices (BMPs) to the maximum extent practicable (MEP). MS4 Permittees have their own development standards, also known as Low Impact Development (LID)/post-construction standards that include a hydromodification component. The MS4 permits also require specific design concepts for LID/post-construction BMPs in the early stages of a project during the entitlement and CEQA process and the development plan review process.

For more information on which Phase I MS4 Permit this project applies to, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/water_issues/storm_water/municipal_permits/

For more information on the Phase II MS4 permit and who it applies to, visit the State Water Resources Control Board at:
http://www.waterboards.ca.gov/water_issues/programs/stormwater/phase_ii_municipal.shtml

**Industrial Storm Water General Permit**
Storm water discharges associated with industrial sites must comply with the regulations contained in the Industrial Storm Water General Permit Order No. 2014-0057-DWQ. For more information on the Industrial Storm Water General Permit, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/water_issues/storm_water/industrial_general_permits/index.shtml

**Clean Water Act Section 404 Permit**
If the project will involve the discharge of dredged or fill material in navigable waters or wetlands, a permit pursuant to Section 404 of the Clean Water Act may be needed from the United States Army Corps of Engineers (USACE). If a Section 404 permit is required by the USACE, the Central Valley Water Board will review the permit application to ensure that discharge will not violate water quality standards. If the project requires surface water drainage realignment, the applicant is advised to contact the Department of Fish and Game for information on Streambed Alteration Permit requirements. If you have any questions regarding the Clean Water Act Section 404 permits, please contact the Regulatory Division of the Sacramento District of USACE at (916) 557-5250.

**Clean Water Act Section 401 Permit – Water Quality Certification**
If an USACE permit (e.g., Non-Reporting Nationwide Permit, Nationwide Permit, Letter of Permission, Individual Permit, Regional General Permit, Programmatic

[1] Municipal Permits = The Phase I Municipal Separate Storm Water System (MS4) Permit covers medium sized Municipalities (serving between 100,000 and 250,000 people) and large sized municipalities (serving over 250,000 people). The Phase II MS4 provides coverage for small municipalities, including non-traditional Small MS4s, which include military bases, public campuses, prisons and hospitals.

General Permit), or any other federal permit (e.g., Section 10 of the Rivers and Harbors Act or Section 9 from the United States Coast Guard), is required for this project due to the disturbance of waters of the United States (such as streams and wetlands), then a Water Quality Certification must be obtained from the Central Valley Water Board prior to initiation of project activities. There are no waivers for 401 Water Quality Certifications. For more information on the Water Quality Certification, visit the Central Valley Water Board website at: https://www.waterboards.ca.gov/centralvalley/water_issues/water_quality_certification/

**Waste Discharge Requirements – Discharges to Waters of the State**

If USACE determines that only non-jurisdictional waters of the State (i.e., "non-federal" waters of the State) are present in the proposed project area, the proposed project may require a Waste Discharge Requirement (WDR) permit to be issued by Central Valley Water Board. Under the California Porter-Cologne Water Quality Control Act, discharges to all waters of the State, including all wetlands and other waters of the State including, but not limited to, isolated wetlands, are subject to State regulation. For more information on the Waste Discharges to Surface Water NPDES Program and WDR processes, visit the Central Valley Water Board website at:https://www.waterboards.ca.gov/centralvalley/water_issues/waste_to_surface_water/

Projects involving excavation or fill activities impacting less than 0.2 acre or 400 linear feet of non-jurisdictional waters of the state and projects involving dredging activities impacting less than 50 cubic yards of non-jurisdictional waters of the state may be eligible for coverage under the State Water Resources Control Board Water Quality Order No. 2004-0004-DWQ (General Order 2004-0004). For more information on the General Order 2004-0004, visit the State Water Resources Control Board website at: https://www.waterboards.ca.gov/board_decisions/adopted_orders/water_quality/2004/wqo/wqo2004-0004.pdf

**Dewatering Permit**

If the proposed project includes construction or groundwater dewatering to be discharged to land, the proponent may apply for coverage under State Water Board General Water Quality Order (Low Threat General Order) 2003-0003 or the Central Valley Water Board's Waiver of Report of Waste Discharge and Waste Discharge Requirements (Low Threat Waiver) R5-2018-0085. Small temporary construction dewatering projects are projects that discharge groundwater to land from excavation activities or dewatering of underground utility vaults. Dischargers seeking coverage under the General Order or Waiver must file a Notice of Intent with the Central Valley Water Board prior to beginning discharge.

For more information regarding the Low Threat General Order and the application process, visit the Central Valley Water Board website at: http://www.waterboards.ca.gov/board_decisions/adopted_orders/water_quality/2003/wqo/wqo2003-0003.pdf

For more information regarding the Low Threat Waiver and the application process, visit the Central Valley Water Board website at: https://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/waivers/r5-2018-0085.pdf

**Limited Threat General NPDES Permit**

If the proposed project includes construction dewatering and it is necessary to discharge the groundwater to waters of the United States, the proposed project will require coverage under a National Pollutant Discharge Elimination System (NPDES) permit. Dewatering discharges are typically considered a low or limited threat to water quality and may be covered under the General Order for *Limited Threat Discharges to Surface Water* (Limited Threat General Order). A complete Notice of Intent must be submitted to the Central Valley Water Board to obtain coverage under the Limited Threat General Order. For more information regarding the Limited Threat General Order and the application process, visit the Central Valley Water Board website at: https://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/general_orders/r5-2016-0076-01.pdf

**NPDES Permit**

If the proposed project discharges waste that could affect the quality of surface waters of the State, other than into a community sewer system, the proposed project will require coverage under a National Pollutant Discharge Elimination System (NPDES) permit. A complete Report of Waste Discharge must be submitted with the Central Valley Water Board to obtain a NPDES Permit. For more information regarding the NPDES Permit and the application process, visit the Central Valley Water Board website at: https://www.waterboards.ca.gov/centralvalley/help/permit/

If you have questions regarding these comments, please contact me at (916) 464-4709 or Greg.Hendricks@waterboards.ca.gov.

Greg Hendricks

## AGENCY LETTER 4: GREG HENDRICKS, CENTRAL VALLEY REGIONAL WATER QUALITY CONTROL BOARD

### Response to Comment Agcy 4-1

This is an introductory comment. The County acknowledges that the Central Valley Regional Water Quality Control Board is delegated with the responsibility of protecting the quality of surface and groundwaters of the state. Comment noted.

### Response to Comment Agcy 4-2

The commenter describes the overall Basin Plan policies and states that the antidegradation analysis is a mandatory element in the NPDES and WDR permitting process. Comment noted. The commenter states that the DEIR should evaluate potential impacts to both surface and groundwater quality. These impacts are analyzed in detail in Chapter 4.8 of the DEIR.

### Response to Comment Agcy 4-3

The commenter provides information on permitting requirements, which are addressed in Sections 4.4 and 4.8 of the DEIR, including the commenter's referenced Construction Storm Water General Permit (pages 4.8-27, 4.8-52), Industrial Storm Water General Permit (pages 4.8-30, 4.8-53), Clean Water Act Section 404 Permit (pages 4.4-40, 4.4-91), Clean Water Act Section 401 Permit – Water Quality Certification (page 4.4-91), Waste Discharge Requirements (pages 4.8-29, 4.8-52), Dewatering Permit (page 4.8-31), and Limited Threat General NPDES Permit (pages 4.8-30, 4.8-52). Comment noted.

Nevada City, CA 95959-7902

Via email
Idaho.MMEIR@co.nevada.ca.us

**COMMENTS ON DRAFT ENVIRONMENTAL IMPACT REPORT (EIR)**
**IDAHO-MARYLAND MINE PROJECT, NEVADA COUNTY**

Agcy 5-1

Central Valley Regional Water Quality Control Board (Central Valley Water Board) staff reviewed the December 2021 Draft Environmental Impact Report (Draft EIR) Volume I of X (Chapters 1-8) for the Idaho-Maryland Mine Project (the Project). The Regional Water Quality Control Boards are delegated with the responsibility of protecting the quality of surface and groundwaters of the state.

Central Valley Water Board staff assumes that the project applicant, Rise Grass Valley, Inc., (Rise Grass Valley) will continue to proceed with County permits and authorizations prior to seeking the necessary approval/permits from the Central Valley Water Board. Therefore, our comments address the adequacy of the Draft EIR as a responsible agency and provide clarification of potential Central Valley Water Board concerns and regulatory requirements regarding water quality.

Central Valley Water Board staff have the following comments.

Agcy 5-2

1. **Approach to Centennial Industrial Site Baseline**. Pages 1-3 through 1-7. The California Department of Toxic Substances Control (DTSC) is the lead regulatory agency for the Centennial Industrial Site Cleanup. Central Valley Water Board staff will assist DTSC with ensuring that the Centennial Industrial Site investigation and cleanup proceeds regardless of the status of the proposed Project.

Agcy 5-3

2. **RoWD and WDRs.** Pages 2-78-81. As indicated in Table 2-1 Mitigation Measures 4.8-1(a), (b), (c), (d) and 4.8-1(e), Rise Grass Valley will need to obtain several different permits from the Central Valley Water Board prior to beginning operations. This includes a permit for the water treatment plant discharge via submittal of a Notice of Intent (NOI) and obtaining a Notice of Applicability (NOA) in the Limited Threat Discharge Permit, submittal of a Report of Waste Discharge (RoWD) and obtaining Waste Discharge Requirements (WDRs) for both the surface impoundment and construction of the engineered fill areas prior to

discharging any mining waste[1], and submitting a NOI for coverage under the Industrial General Permit and prepare a Industrial Stormwater Pollution Prevention Plan. After receipt of the NOIs and RoWDs, Central Valley Water Board staff will evaluate the documents and their applicability for the appropriate permits when they are submitted. The Central Valley Water Board may require modifications to the water treatment system, surface impoundment and mining operations as well as monitoring to ensure the protection of water quality. All permitting requirements are expressly noted in the Draft EIR as mitigation measures. Under Water Code §13263.1, the Central Valley Water Board must determine that the proposed mining waste discharge is consistent with a waste management strategy that prevents the pollution or contamination of the waters of the state, particularly after closure of any waste management unit for mining waste, before issuing any permits.

3. **Ongoing Waste Characterization.** Under Water Code §13260(k), the RoWD must also include a report on the physical and chemical characteristics of the waste that could affect its potential to cause pollution or contamination as well as a report that evaluates the potential of the discharge of the mining waste to produce, over the long term, acid mine drainage, the discharge or leaching of heavy metals, or the release of other hazardous substances. The WDRs will require continuous and routine characterization and classification (Cal. Code Regs., Tit. 27 §22480(b)) of the mining waste to evaluate any possible changes in the geological or geochemical nature of the waste. Rise Grass Valley will need to address any changes in waste classification.

Agcy 5-4

Central Valley Water Board staff anticipate that to comply with Water Code §13260(k) and ensure protection of water quality as part of the RoWD/WDR process, the Central Valley Water Board will require Rise Grass Valley to prepare and implement a Waste Characterization Plan (Characterization Plan) comparable to the ASUR Plan[2] identified in the Draft EIR. The purpose of the Characterization Plan is to continually evaluate the different forms of mining wastes and to appropriately classify these wastes as Group A, Group B, or Group C based on an assessment of the potential risk of water quality degradation posed by each waste. Through the WDRs, these wastes will be required to be managed, treated, stored, or disposed of in a manner that is protective of water quality.

[1] The Mining Waste Management Regulations define "mining waste" as "waste from the mining and processing of ores and mineral commodities. Mining waste includes: (1) overburden; (2) natural geologic material which have been removed or relocated but have not been processed (waste rock); and (3) the solid residues, sludges, and liquids from the processing of ores and mineral commodities." Cal. Code Regs., tit. 27, § 22480(a).
[2] Asbestos, Serpentinite, and Ultramafic Rock Management Plan (ASUR Plan). See page 3-19 of the Draft EIR.

Mining waste that is characterized and classified as Group C (i.e., discharge of these wastes would be in compliance with water quality objectives other than turbidity) could be used as engineered fill[3] with limited regulatory restrictions. During the RoWD/WDR process, the Central Valley Water Board will establish the specific methods, volumes, and frequency of characterization and determine the appropriate requirements for the WDR.

4. **Engineered Fill.** Page 3-29 of the Draft EIR indicates that mining waste used as engineered fill would be considered a Group C mining waste. The language leaves the reviewer with the impression that because mining waste is used as engineered fill, it is considered a Group C mining waste. This is not correct. Mitigation Measure 4.8-1(e) provides a better summation of the accepted regulatory approach.

**Agcy 5-5**

Sand tailings, waste rock, backfill material, or other combinations being proposed for engineered fill will need to be characterized as Group C mining waste (e.g. page 4.8-50) prior to its use as engineered fill. Rise Grass Valley will need to characterize and classify mining waste in its correct California Code of Regulations Title 27 waste group, which will dictate how the waste must be managed, contained, or used. The Draft EIR should be revised to address this comment.

5. **Off-Site Sales of Waste Rock.** Page 1-7 of the Draft EIR states that "…*this EIR anticipates that waste rock from the Brunswick Industrial Site could also be sold as engineered fill to local and regional markets to be used as aggregate in roadway and construction projects*. For mining waste to be used for off-site purposes, Rise Grass Valley would first need to confirm that the waste would not pose a threat to water quality or that the potential threat to water quality could be mitigated (Cal. Code Regs., Tit. 27 §22480(c) and §22480(d)) for its proposed use. Rise Grass Valley will need to use the anticipated Characterization Plan to address this issue.

**Agcy 5-6**

Central Valley Water Board staff is somewhat concerned with the general assumption in the Draft EIR that a significant volume of the mining waste produced during the life of the Project will be suitable for off-site sale and use in local and regional markets as construction aggregate with limited regulatory restrictions (i.e., Group C mining waste). While the geochemical nature of the mining waste may prove to be suitable for construction aggregates, the alternative scenario that the mining waste is not suitable for off-site use should be examined. How would this affect the economic or operational aspects of the

[3] The use of mining waste as engineered fill is proposed for potential industrial pad development at the Centennial and Brunswick Industrial sites (Draft EIR, page 1-2) for the first 10-11 years of the Project and for local and regional markets for sale as construction aggregate and fill (Draft EIR, page 1-3) for the remainder of the Project.

Project? Rise Grass Valley should assess any operational constraints, such as not mining geological material that may produce water quality issues, challenges associated with the expanded use of cemented paste backfill[4] as a method of waste disposal, and the anticipated operational or economic costs resulting from the inability to utilize mining waste for off-site sale as construction aggregate. The Draft EIR should be revised to address this comment.

Agcy 5-7

6. **Clay Lined Settling Pond.** The Draft EIR indicates that the existing clay lined pond can be covered with a geomembrane liner to ensure seepage does not occur from the pond (Draft EIR, pages 2-79 and 3-17). While this proposal may meet minimum California Code of Regulations Title 27 prescriptive standards, it may not meet the potentially more stringent California Code of Regulations Title 27 performance standards. The Central Valley Water Board may require a more stringent design in a case where it concludes that the minimum design will not provide adequate protection to a given body of groundwater. The Central Valley Water Board will address this issue during the RoWD/WDR phase.

Agcy 5-8

7. **Water Quality Specific Financial Assurances.** While the Draft EIR references requirements for California's Surface Mining and Reclamation Act (SMARA) financial assurance(s), there will be water quality specific financial assurances for closure and post-closure maintenance of mining units as required by Title 27, section 22510. Although there is some discussion of potential overlap between the SMARA financial assurances (Draft EIR, page 4.8-30), water quality specific financial assurances will focus on water within the mine workings, groundwater, and mine water that ultimately discharges from the Project after mine closure. This may include the need for long-term water treatment of mine-related discharges. These financial assurances are separate and distinct from the SMARA financial assurances discussed in pages 3-42, 3-47, 4.8-30, and 4.9-20. This issue will be addressed during the RoWD/WDR phase.

Agcy 5-9

8. **Temporary or Short-Term Shutdowns.** Staff could not locate a discussion in the Draft EIR of temporary or short-term shutdown plans (Short-Term Shutdown Plan). Rise Grass Valley should anticipate temporary or short-term shutdowns over the life of the Project due to changes in economic conditions, technical issues, changes in management, etc. The WDRs will require that Rise Grass Valley prepare a Short-Term Shutdown Plan that identifies mitigation measures to protect water quality and the environment. The plan will include financial assurances to ensure that there are adequate funds to perform basic operations and maintenance until mining resumes or closure takes place.

Agcy 5-10

9. Staff could not locate a discussion in the Draft EIR on how the applicant intends to address/mitigate/ or take responsibility for any post-mining water quality issues. The Draft EIR should be revised to address anticipated post-mining

[4] Cemented paste backfill may/could be considered treatment under Title 27, section 22480(d).

water quality issues and whether the mine will require long-term oversight to ensure water quality conditions comply with applicable regulatory requirements.

**Agcy 5-11**

10. The Low-threat permit referenced throughout the Draft EIR has been rescinded. General Waste Discharge Requirements/NPDES Permit for Limited Threat Discharges to Surface Waters, Order R5-2022-0006/NPDES Permit No. CAG995002 was adopted on 17 February 2022.[5]

Please contact Jeff Huggins at (916) 464-4639 or Jeff.Huggins@waterboards.ca.gov with any questions regarding the contents of this letter. We are available to meet with you if you would like to discuss applicable Water Board requirements or potentially applicable permits.

## AGENCY LETTER 5: JEFF HUGGINS, CENTRAL VALLEY REGIONAL WATER QUALITY CONTROL BOARD

### Response to Comment Agcy 5-1

The comment is introductory and correctly assumes that the applicant will continue to proceed with County permits prior to seeking the necessary approval/permits from the Central Valley Water Board. Comment Noted.

### Response to Comment Agcy 5-2

Comment Noted. Please see Master Response 4 - Cleanup Project is a Separate Project Under CEQA.

### Response to Comment Agcy 5-3

The comment is informational in nature, generally summarizing the permitting requirements for the project and acknowledging that the requirements are identified in the EIR as mitigation measures. The County and applicant understand the Central Valley Water Board's role in the process and appreciate the comments.

### Response to Comment Agcy 5-4

Report of Waste Discharge (RoWD) permitting requirements are set forth in Mitigation Measure 4.8-1(e) of the DEIR. In response to the comment, Mitigation Measure 4.8-1(e) is hereby modified in the Final EIR to include the commenter's clarifications on the requirements for ongoing waste characterization in the approved WDR.

Page 4.8-53, Mitigation Measure 4.8-1(e), is hereby revised, as follows:

> 4.8-1(e) The applicant shall submit a RoWD and obtain WDRs from the Central Valley RWQCB for construction of the engineered fill areas. The WDR permit shall be received by the applicant prior to initiating any engineered fill placement activities at the Centennial or Brunswick Industrial Sites. Proof of coverage shall be provided to the Nevada County Public Works Department. As part of this process, the RWQCB will determine the appropriate mining waste classification for the proposed engineered fill, and will consider the following factors: (1) whether the waste contains hazardous constituents only at low concentrations; (2) whether the waste has no or low acid generating potential; and (3) whether, because of its intrinsic properties, the waste is readily containable by less stringent measures. The engineered fill areas shall be constructed in accordance with the Title 27 specifications, pursuant to the mining waste classification determined by the RWQCB. The applicant shall submit to the Nevada County Planning Department a copy of the RoWD and evidence of the applicant's receipt of WDRs prior to the placement of fill or fill site preparation disturbance at the Brunswick Industrial Site and Centennial Industrial Site. <u>The RoWD must also include a report on the physical and chemical characteristics of the waste, in compliance with Water Code section 13260(k), that could affect its potential to cause pollution or contamination as well as a report that evaluates the potential of the discharge of mining waste to produce, over the long term, acid mine drainage, the discharge or leaching of heavy metals, or the release of other hazardous substances. The WDR's will require continuous and routine characterization and classification (Cal Code regs Title 27 section 22480(b)) of the mining waste to evaluate any possible changes in the geological or geochemical nature of the waste. The applicant shall prepare and implement a Waste Characterization Plan (Characterization Plan) which shall be incorporated into the approved WDR. The purpose of the Characterization Plan is to</u>

> continually evaluate the different forms of mining wastes and to appropriately classify these wastes as Group A, Group B, or Group C based on an assessment of the potential risk of water quality degradation posed by each waste. Through the WDR these wastes shall be managed, treated, stored, or disposed of in a manner that is protective of water quality. The applicant shall not sell or utilize waste rock and tailings from the Project for construction aggregate or fill purposes offsite (i.e. sites other than the applicant's Brunswick and Centennial sites) unless such material has been tested and confirmed to qualify as Group C mining waste under California Code of Regulations Section 22480 and the approved WDR. The specific methods, volumes and frequency of characterization shall be established in the approved WDR.

The above changes are provided in response to the comment for clarification purposes and do not alter the conclusions of the DEIR.

## Response to Comment Agcy 5-5

Comment noted. Page 3-29 of the DEIR has been modified to delete the sentence, "as the engineered fill would be considered a Group C mining waste." , as shown below.

Mitigation Measure 4-8-1(e) has been modified to clarify the requirement that the applicant shall not sell or utilize waste rock and tailings from the project for construction aggregate or fill purposes offsite (i.e., sites other than the applicant's Brunswick and Centennial sites) unless such material has been tested and confirmed to qualify as Group C mining waste under California Code of Regulations Section 22480 and the approved WDR which will establish the specific methods, volumes and frequency of characterization. See revised language of Mitigation Measure 4.8-1(e) in Response to Comment Agcy 5-4 above.

Page 3-29 of the DEIR is hereby revised as follows:

> The applicant will be required as part of the project to submit a Report of Waste Discharge (RoWD) and obtain Waste Discharge Requirements (WDRs) from the Regional Water Quality Control Board (RWQCB) for construction of the engineered fill areas~~, as the engineered fill would be considered a Group C mining waste.~~[3] Percolation of precipitation into the fill areas is expected to be minimal because the engineered fill would be graded and compacted to allow runoff to be conveyed to the detention basins. The WDRs would specify appropriate monitoring and limitations to prevent the discharge of water containing any constituents outside of applicable water quality standards.

The above minor change is provided for clarification purposes and does not alter the analysis, nor conclusions in the DEIR.

## Response to Comment Agcy 5-6

Mitigation Measure 4.8-1(e) has been modified to clarify the requirements for a Characterization Plan in the approved WDR and Group C mining waste requirement for offsite material (See Response to Comment Agcy 5-5, and Response to Comment Agcy 5-4 for the revised mitigation measure language).

Economic costs are not required to be analyzed under CEQA. Please see Master Response 1 - Non-EIR/Administrative Issues and Master Response 2 - Social and Economic Impacts. Testwork performed on rock samples from the project site, and the specific process used to produce sand tailings indicate that the project's waste rock and sand tailings will meet Class C Mining Waste standards, such that the situation posed by the commenter is not reasonably expected to occur. Moreover, the project's ASUR plan includes advanced mine planning such that the mine operator will have core samples of rock material prior to mining in new areas of the project site with a

different rock chemistry. As such, the mine operator will have advanced information on rock chemistry and thus will be able to avoid mining in rock material that is unsuitable for construction aggregate, if large amounts of unsuitable material are unexpectedly discovered.

Please also see Master Response 11 - Engineered Fill Utilized in Local and Regional Construction Markets.

## Response to Comment Agcy 5-7

The comment does not address the adequacy of the DEIR. The County and applicant understand that the Central Valley Water Board will conduct review of the project, including the clay-lined pond, during the RoWD/DWR phase. Comment noted.

## Response to Comment Agcy 5-8

The comment does not address the adequacy of the DEIR. The County and applicant understand that the Central Valley Water Board will conduct review of the project, including the noted financial assurances, during the RoWD/DWR phase. Comment noted.

## Response to Comment Agcy 5-9

The comment does not address the adequacy of the DEIR. The County and applicant understand that the Central Valley Water Board will conduct review of the project, including the noted topic of temporary shutdowns, during the RoWD/DWR phase. Comment noted.

## Response to Comment Agcy 5-10

As stated on page 4.8-51 of the DEIR, after mining is completed, and as underground mine workings fill with groundwater, water from the underground mine workings would begin to seep from the existing drains. The water that would seep from the underground workings is anticipated to have similar water quality to the water that currently discharges from the existing drains. Specifically, it may contain elevated levels of iron and manganese. Therefore, the conditions after mining is completed would be similar to existing, or baseline, conditions, such that re-activation of the seeps would not represent a potentially significant impact under CEQA. The mine operator will work with the CVRWQCB at the time of mine closure to implement any measures that may be required at that time to address re-activation of the existing baseline condition seeps.

## Response to Comment Agcy 5-11

In response to the comment, relevant sections of Chapter 4.4, Hydrology and Water Quality, of the DEIR are hereby revised in this FEIR reference the current Order R5-20022-006 for NPDES Permit No. CAG995002, as follows:

Page 4.8-28, Section 4.8.3, Regulatory Context, is hereby revised as follows:

> General Permit for Limited Threat Discharges to Surface Waters
>
> The Limited Threat General Order (R5-~~2016-0076-01~~2022-0006) is a general Waste Discharge Requirements permit for Limited Threat Discharges to Surface Water. The discharge of treated water from the proposed mine into South Fork Wolf Creek is anticipated to be covered as a Tier 3 discharge of hard rock mine wastewater. Under Table 3 of the Limited Threat Discharge permit, Tier 3 discharges to surface water that are greater than 250,000 gpd (greater than 175 gpm) and/or that are longer than four months are allowed if the water to be discharged (with or without treatment) meets the applicable screening levels in the permit.
>
> Effluent limitations are listed in Section V and screening levels are listed in Attachment I of the Low Threat Discharge permit. Rise will be required to file a Notice of Intent (NOI) for

coverage under the Limited Threat Discharge permit, which will include a detailed description of the dewatering, treatment, and discharge components of the project. A Monitoring and Reporting Program (MRP) will also be required pursuant to the General Order, Attachment C. The MRP will specify monitoring station locations, sampling frequencies and methods, and monitoring report submittal requirements to the Regional Board.

Page 4.8-45, Section 4.8.4, Impacts and Mitigation Measures, Impact 4.8-1, is hereby revised as follows:

Ongoing monitoring of influent and effluent (i.e., treated water) will be required by the State, in order for the applicant to receive coverage under the State's Limited Threat Discharge Permit (General Order R5-~~2016-0076~~2022-0006; NPDES No. CAG995002). Monitoring of treated water would occur at a location specified by the State prior to the point of discharge at South Fork Wolf Creek. The owner will be required to submit quarterly monitoring reports to the State RWQCB, demonstrating compliance with the maximum daily effluent limitations specified in Section V of the NPDES permit. Compliance with the water quality standards and waste discharge requirements in Order No. R5-~~2016-0076~~2022-0006 would prevent any degradation of surface water quality due to dewatering.

Page 4.8-52, Mitigation Measure 4.8-1(a), first sentence, is hereby revised as follows:

*4.8-1(a)* *The applicant shall submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) for coverage under the Limited Threat Discharge permit (General Order R5-~~2016-0076~~2022-0006; NPDES No. CAG995002), at least six months prior to construction of the water treatment system; and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin and provided to Nevada County Planning Department.*

Page 4.8-79, Impact 4.8-6, first paragraph, is hereby revised as follows:

The current water quality control plan for the region is the Water Quality Control Plan for the Sacramento and San Joaquin River Basins, which is also referred to as the Basin Plan (CVRWQCB, 2019). The project would be required to operate under an applicable WDR permit from the CVRWQCB for placement of any waste material on land. The dewatering discharge to South Fork Wolf Creek would also need to comply with the requirements of the applicable NPDES permit Order R5-~~2016-0076~~2022-0006 (NPDES No. CAG995002) for Limited Threat Discharges to Surface Water as a Tier 3 discharge. The WDR and NPDES requirements ensure that the project would not conflict with or obstruct implementation of the Basin Plan.

The above minor changes are for clarification purposes and do not alter the adequacy of the analysis contained in the DEIR, nor its conclusions.

COMMENT ON THE DRAFT ENVIRONMENTAL IMPACT REPORT FOR THE IDAHO-MARYLAND MINE PROJECT – DATED DECEMBER 2021 (STATE CLEARINGHOUSE NUMBER: 2020070378)

Dear Mr. Kelley:

The Department of Toxic Substances Control (DTSC) received the Draft Environmental Impact Report (DEIR) for the Idaho-Maryland Mine Project (Project). The Lead Agency is receiving this notice from DTSC because the Project includes the possible use of the nearby Centennial M-1 property as a repository for mine waste if the Project proceeds.

**Agcy 7-1**

The owner of the Centennial M-1 property is under a voluntary cleanup agreement with DTSC to address existing mine waste at this site via a remedial action plan that is currently under review. If approved, the cleanup of the Centennial M-1 site includes consolidating existing mine waste with contaminant concentrations above commercial/industrial cleanup levels and encapsulating this material on the property with on-site soils that are protective of human health under the anticipated commercial/industrial future use. In addition, the protective surface soils will be graded to ensure runoff is directed away from the encapsulated material and towards a retention basin that will also be constructed to protect Wolf Creek which is located nearby.

**Agcy 7-2**

To ensure the long-term safety and integrity of the proposed remediation, any waste rock brought to the Centennial M-1 site from the Idaho-Maryland Mine must be sampled to ensure it meets the cleanup levels for the Centennial M-1 site achieved during the

Printed on Recycled Paper

cleanup effort. In addition, the material must be placed in such a way as to ensure the integrity and function of the cap to direct surface water away from the buried contamination. The protocol and frequency of sampling waste material from the Idaho-Maryland Mine and the frequency of inspections of the Centennial M-1 site have yet to be determined. These efforts may be outlined in the Operation and Maintenance (O&M) Agreement with DTSC that will be a part of the Centennial M-1 remediation or they be approved in a separate stand-alone document. Any specifications, work plans, or reports regarding placement of material on the Centennial M-1 must be reviewed and approved by DTSC under an O&M or other agreement with DTSC. DTSC is providing this letter to ensure the County is aware of these general requirements as they do not appear to be discussed in the DEIR.

DTSC appreciates the opportunity to review and comment on the DEIR for the Project. If you have any questions, please contact me at (916) 255-3591 or via email at Dean.Wright@dtsc.ca.gov.

Sincerely,

Dean Wright

**RE: COMMENTS ON THE IDAHO-MARYLAND MINE PROJECT DRAFT ENVIRONMENTAL IMPACT REPORT (DECEMBER 2021) (SCH# 2020070378), NEVADA COUNTY, CALIFORNIA**

Dear Mr. Kelley:

**Agcy 8-1**

The City of Grass Valley has completed review of the Draft Environmental Impact Report (DEIR) for the Idaho-Maryland Mine Project (IMMP) and prepared the following comments. In summary, the DEIR is extraordinarily long (over 1,000 pages not including technical appendices), and much of its contents are very thorough. In addition to my review, the City was assisted in its review by Dr. Jeff Harvey, Ph.D., Principal & Senior Scientist with the Harvey Consulting Group for CEQA adequacy, Project Description, Hydrology and Alternatives topics. Paul Miller, Principal and Senior Air Quality and Noise Analyst, and Dan Jones, Senior Air Quality and Noise Analyst with The RCG Group for the Air Quality, Greenhouse Gas Emissions, Health Risks and Noise topics, and John Kain, AICP, Principal and Senior Transportation Planner, and Marlie Whiteman, P.E., Senior Transportation Engineer, with Urban Crossroads, Inc. for the Transportation and Vehicle Miles Travelled topics.

As detailed in our comments below, key aspects of this proposed 80-year mining and industrial development project – including air quality, greenhouse gases and traffic, and consideration of alternatives that may reduce or avoid potentially significant impacts to the City and surrounding County areas – are not accurately or adequately assessed. Corrections needed to these analyses are very likely to conclude with findings of greater impact levels than are now reported, and therefore a need for additional mitigation measures, and/or consideration of other project alternatives. This letter highlights technical inadequacies of the DEIR based on the CEQA statute, CEQA Guidelines and published court decisions interpreting CEQA.

**CHAPTER 3: PROJECT DESCRIPTION**

**Agcy 8-2**

PD-1) The applicant's request for an 80-year permit is extraordinary and makes this truly a multi-generational project. It is reasonable to expect that a lot is going to change in 80 years, possibly including mining methods, regulatory standards, market demand for gold, transportation methods and more. The County needs to consider a shorter permit time period, with an ability to renew the permit based upon an updated environmental review that reflects conditions and standards decades in the future. We suggest 30-years maximum permit period, which is still a major commitment to a single large industrial use. In addition, the County should consider a condition of approval requiring an Adaptive Management Process under which the project gets reviewed periodically (every 10 years), with additional environmental compliance and mitigation requirements added to the permit conditions as needed.

**Agcy 8-3**

PD-2) Likewise, the size of the project needs to be reconsidered. The 1,000 tons per day goal may be optimal for the applicant, but it is not optimal for the community as it requires off-site hauling through community areas and the City in 20 to 25 ton trucks from 6:00 AM to 10:00 PM seven days per week for 80 years. We recommend a cap of 500 tons per day or less, and no nighttime hauling activity. This would reduce truck traffic generation, noise, air quality and greenhouse gas emissions, energy and fuel use, and the volume of residual material to be disposed of by half – a very significant reduction in the impacts of this proposed industrial operation.

**Agcy 8-4**

PD-3) The proposed hauling operations need to clearly note that this part of the operation will include the loading, dumping, spreading, and compacting of waste materials. (See related comment in the Noise section below). Page 3-40 of the DEIR states "Hauling and dumping of engineered fill at the Centennial Industrial Site would occur between 6:00 AM – 10:00 PM." The hauling and dumping of engineered fill are construction activities that are intended to create industrial development pads rather than a mining activity, and as such, should be limited to the construction hours of the City's Noise Ordinance (prohibits construction noise between the hours of 7 pm and 7 am, or on Sundays) and should discuss how this proposed plan affects the goals of the Safety and Noise Elements of the County's General Plan, rather than just mentioning it on page 3-2.

**Agcy 8-5**

PD-4) The County may also consider splitting the Centennial Site operations off as a separate project and conduct environmental review and permitting independently. If the engineered fill can be used for deep mine backfill or transported to local and regional markets for use in construction projects (DEIR, page 3-26), the backfill at the Centennial Industrial Site does not need to be a component of the mining operation.

| | | |
|---|---|---|
| **Agcy 8-6** | PD-5) | On page 3-18 in the discussion of the water treatment process and system it is noted that monitoring reports are required to be submitted quarterly. Please include the timing intervals for monitoring samples to be obtained. We suggest that at a minimum sampling should be done monthly for at least the first year, and quarterly thereafter if the first-year results demonstrate compliance with the maximum daily effluent limitations. |
| **Agcy 8-7** | PD-6) | On page 3-19 in the third paragraph of the discussion of Mine Development (Tunneling) it is stated that the underground transport of barren rock will be done using electric or diesel-powered load/haul/dump vehicles. We suggest that the County should require all such vehicles to be electric-powered so that diesel exhaust emissions underground are eliminated. |
| **Agcy 8-8** | PD-7) | On page 3-19 in the second paragraph of the discussion of Gold Mineralization Production, it is stated that 50 percent of mineralization would be returned to the underground mine as backfill, and the remainder would be used as engineered fill. This is not for the life of the project, as the engineered fill process only extends an estimated 5 to 12 years for the Centennial and Brunswick sites. Please describe what happens to the additional 50 percent (over 150,000 tons per year) for the tens of decades after the engineered fill is completed. |
| **Agcy 8-9** | PD-8) | On page 3-21 in the second paragraph of the discussion of the ventilation exhaust system and underground support systems, please confirm that these include back-up generators and an alarm system in the event of a power outage. |
| **Agcy 8-10** | PD-9) | Starting on page 3-26 in the discussion of Engineered Fill Transport, it is stated that engineered fill would be stored at the Brunswick site and/or transported to local and regional construction markets. Like gold, the market for engineered fill can fluctuate substantially over periods of years. There needs to some defined maximum volume that can be stored at the Brunswick site, the storage method described, and a discussion of what happens when "local and regional construction markets" have low demand for these fill materials for a prolonged period of time. |
| **Agcy 8-11** | PD-10) | On page 3-28 in the first paragraph of the discussion of explosives, it is stated that the explosives supplier will have a "sufficient" insurance policy. Please define the term "sufficient" in this context and provide details regarding the events that will be covered so the sufficiency of the insurance may be accurately assessed. |
| **Agcy 8-12** | PD-11) | On page 3-33 in the first paragraph of the discussion of the Potable Water Pipeline, please confirm that the pipeline construction and extensions to willing residents will occur prior to the commencement of dewatering of the mine. |

**Agcy 8-13**

PD-12) On page 3-42 in the discussion of Mine Rescue and Emergency Response, please confirm that the mine-rescue team will be a part of the mining workforce on site.

**Agcy 8-14**

PD-13) On page 3-42 in the discussion of the Reclamation Plan, (and in Table 3-10 on page 3-46) the County should require that reclamation include demolition and removal of the above ground facilities and structures, subject to review if the buildings are inspected and determined to be of commercial value. These facilities and structures will be decades old at the time of reclamation and are unlikely to be in a condition that supports unknowable post-mining industrial uses of the property.

**Agcy 8-15**

PD-14) On page 3-52 in Table 3-11, a fact check: we believe that the RWQCB rather than the SWRCB Division of Water Rights has jurisdiction for all six of the permits listed for those agencies.

**CHAPTER 4.3: AIR QUALITY AND GREENHOUSE GAS EMISSIONS**

**Agcy 8-16**

AQ-1) The DEIR and Health Risk Assessment lack details of sensitive receptors that were considered for evaluating potential localized health impacts from the project. Page 4.3-11 of the DEIR states "At the Brunswick Industrial Site, rural residences are located to the north, west, east, and south. The nearest residence is north of East Bennett Road, approximately 100 feet from the Brunswick Industrial." Page 4.3-79 of the DEIR states "The maximally exposed receptor was estimated to be the nearest existing residence, which is north of the Brunswick Industrial Site." However, there is no map, figure, or other detailed information showing the sensitive receptors that were considered for evaluating potential localized health impacts from the Project in the DEIR or in the Air Quality and Greenhouse Gas Emissions Analysis Technical Report (Dudek, 2020). This information should be added in the Recirculated Draft EIR.

**Agcy 8-17**

AQ-2) The analysis of whether the project would result in wasteful, inefficient, or unnecessary use of energy is inadequate. CEQA Guidelines Section 15126.2, regarding the discussion of energy impacts, states: "*This analysis should include the project's energy use for all project phases and components, including transportation-related energy, during construction and operation.*" The discussion of Impact 4.3-4 (beginning on page 4.3-86) of the DEIR does not disclose the estimated fuel usage (gasoline and diesel) from mobile sources (off-road equipment and on-road transportation sources) associated with construction and operation of the Project. This information should be included to disclose the scale of the Project's usage of petroleum fuel sources. (See Ukiah Citizens for Safety First v. City of Ukiah, (2016) 248 Cal.App.4th 256). The discussion of Impact 4.3-4 should be enhanced to discuss whether this amount of energy usage would be considered wasteful, inefficient, or unnecessary.

AQ-3) The analysis of whether the project would conflict with a State or local plan for renewable energy or energy efficiency is inadequate. Page 4.3-88 of the DEIR states that that the Project would consume approximately 50,000 MWh annually during the 80-year operational life of the Project. Page 4.3-88 of the DEIR states that the Project would be served primarily by grid-supplied electricity, except under conditions when emergency power is required, and standby diesel generators would be used.

**Agcy 8-18**

According to the Nevada County Energy Action Plan (EAP), Nevada County's total consumption in 2017 was approximately 344,000 MWh.[1] The Project's annual energy use would represent an increase of approximately 15 percent in County-wide electricity usage for a single industrial use. As noted on Page 4.3-40 of the DEIR, "*One of the central goals of the EAP is to reduce the projected annual grid supplied electricity use in 2035 by 51 percent…compared to a baseline from the year 2005*." The Project would result in a substantial long-term increase in grid supplied electricity consumption in the County which conflicts with the Nevada County EAP. This energy use should be recognized as a significant impact of the proposed project and mitigation should be incorporated to reduce this impact.

AQ-4) The cumulative energy use impact discussed in 4.3-9 (Page 4.3-102) of the DEIR is difficult to differentiate from the project-level energy analyses (Impacts 4.3-4 and 4.3-5). The impact heading and significance determination statements are written as if they are discussing project-level impacts. The discussion needs to be enhanced to describe the potential cumulative energy use impacts of the Project when viewed together with the energy use of past, present, and reasonably foreseeable future projects.

**Agcy 8-19**

AQ-5) The DEIR lacks mitigation measures for project operations. Page 4.3-67 of the DEIR states "*According to the NSAQMD, unmitigated project generated emissions of ROG $NO_X$ and PM10 that are greater than zero are potentially significant and require mitigation.*" Table 4.3-17 (Maximum Unmitigated Daily Project Emissions) notes that all operational phases of the Project would be potentially significant for ROG, $NO_X$ and PM10 and Page 4.3-70 of the DEIR states "*As shown in Table 4.3-17, daily unmitigated emissions of ROG, NOx and PM10 would be potentially significant (Level A or B) according to the NSAQMD significance criteria; therefore, mitigation is required.*"

**Agcy 8-20**

However, no mitigation measures were implemented for the operational phases of the Project. The NSAQMD states in their *Guidelines for Assessing and Mitigating Air Quality Impacts of Land Use Projects* (*Guidelines*) that "*The lead agency should contact the District office to discuss the mitigations before the lead agency*

[1] Nevada County Energy Action Plan, Accepted by Board of Supervisors 5-0 February 12th, 2019, accessed at: https://www.mynevadacounty.com/DocumentCenter/View/35183/Nevada-County-Energy-Action-Plan

*commits to a final mitigation plan for each project.*" Since the Idaho-Mine Project is not a typical land use project for which the *Guidelines* are intended for and no mitigation measures from the *Guidelines* are applicable to the operational phases of the Project, the NSAQMD should have been (and should be) consulted to discuss mitigation measures that could be applicable to Project operation. The DEIR does not cite any correspondence with the NSAQMD. Thus, it is unclear if the Project will implement mitigation required to reduce potentially significant operational air quality impacts to less than a significant level or require a statement of overriding considerations.

**Agcy 8-21**

AQ-6) The issues addressed above need to be corrected in the Recirculated DEIR as the corrections will result in "Significant New Information" per Section 15088.5 of the CEQA Guidelines.

**CHAPTER 4.8: HYDROLOGY AND STORMWATER**

**Agcy 8-22**

HS-1) The City of Grass Valley is concerned about stormwater flows in the South Fork of Wolf Creek channel that extends through the City and has very limited capacity under baseline conditions. In the discussion of surface water runoff beginning on page 4.8-69, it states: "*The proposed detention basins would hold back the peak flows and release the water at a lower rate and at a later time than currently occurs from those site areas. As a result, the project would reduce peak storm flows in both Wolf Creek and South Fork Wolf Creek.*" This conclusion is based upon a preliminary hydrology assessment and a peer review of that assessment and appears to have been well done. The potential stormwater impact is recognized as significant, and the mitigation measure 4.8-3 (page 4.8-76) is formulated to reduce the potential to "less than significant". The measure requires development of a "Final Drainage Report" which shall be submitted to the Nevada County Planning Department and "*…shall demonstrate that the on-site storm drain systems are sized such that site runoff (in addition to treated mine discharge for the Brunswick Industrial Site) under the post-development condition will not exceed predevelopment levels in the downstream channel(s) during the design storm events.*" Due to the importance of this issue to the City, and the significance of this potential impact, we request the County add a requirement for the Final Drainage Report to also be submitted to the City's Engineer for review and comment.

**CHAPTER 4.9 LAND USE**

**Agcy 8-23**

LU -1) The DEIR fails to acknowledge the applicable City's General Plan as required by Nevada County General Plan Land Use Policies 1.8.1, 1.8.3, 1.8.5, and 1.8.6., and needs to acknowledge that the proposed project is located within the City's adopted Sphere of Influence. The DEIR, which mentions the County's General Plan on page 3-2, should have discussed and analyzed the above-noted policies and the City's General Plan to determine whether those County policies will conflict with, or result in significant land use impacts on, the City.

**CHAPTER 4.10: NOISE AND VIBRATION**

**Agcy 8-24**

NV-1) The noise and vibration mitigation measures lack timing. Mitigation Measure 4.10-4 lacks specific timing requirements for implementation. Mitigation Measure 4.10-4 should be revised to include timing for implementation and require the Ground Vibration Monitoring Program to be developed prior to operation of the mine. The Ground Vibration Monitoring Program should require seismographs to be placed in accordance with the recommendations of the Blasting Report prepared by Precision Blasting Services (i.e., different requirements for different blasting depths). Furthermore, the results of the Ground Vibration Monitoring Program should be required to be submitted to the Nevada County Planning Department for review in a timely manner, reasonable to the County and applicant, to allow for adjustments in project conditions of approval, if warranted by the monitoring data.

**Agcy 8-25**

NV-2) A Recirculated DEIR needs to acknowledge that the hauling operations will include loading and dumping of trucks, and the spreading and compacting of this material. Those are standard construction operations that are tied to the proposed development of pad sites for future industrial use and would occur well beyond standard construction operational hours in most communities and be in violation with the City's noise ordinance that prohibits construction activities that generate significant noise between the hours of 7 pm and 7 am, or on Sundays within 500 feet of a residential zone. Although there are no residential zones within 500 feet of the Centennial site, there are homes in the area and the loading and unloading of material will generate noise. A Recirculated DEIR needs to address any potential conflict with the County's General Plan Safety and Noise Element adopted in October 2014 and the City's Noise Ordinance to adequately address the noise levels to be generated by the full hauling operations. The DEIR needs to fully disclose that the Centennial site operations and site preparation will occur well beyond any typical construction operation and likewise the resulting long-term noise impacts.

**Agcy 8-26**

NV-3) A five or more years-long operation that is active seven days a week and 16+ hours a day cannot be reasonably dismissed as a "temporary noise impact" as it is in section 4.10-1 and on page 4.10-32. It is only short term relative to the requested 80-year mining permit. These noises will reverberate thought the adjacent valleys and hills every day and for many years when other construction activities are not allowed or limited. The impacts must be articulated and mitigated

**Agcy 8-27**

NV-4) Table 4.10-6 is listing Leq values as Lmax and vice versa, for Baseline Ambient Conditions for the Nighttime Column.

**CHAPTER 4.12 TRANSPORTATION**

**EIR TRAFFIC SECTION COMMENTS**

**Agcy 8-28**

T-1) ***Figure 4.12-4 and related LOS analysis / tables*** incorporate stop signs on Idaho Maryland Road that don't exist (intersection 20) – these are also included in the LOS analysis. Please update the figures in the EIR and TIA, along with the LOS analysis and related tables.

**Agcy 8-29**

T-2) ***Vehicle Miles Traveled Standard of Significance*** (page 4.12-27) indicates that VMT impact may be considered less than significant if the Project total weekday VMT / Service Population is equal to or less than 14.3 percent below the subarea mean under baseline conditions and the Project is consistent with the jurisdiction's General Plan. Grass Valley was used as the subarea, which has a Home-Based VMT per worker of 18.6. The 18.6 Grass Valley VMT standard (Table 4.12-4) appears to be sourced from Table A-3 of the Senate Bill 743 Vehicle Miles Traveled Implementation (Fehr & Peers, July 6, 2020). However, the Home-Based Attraction VMT per Employee presented in Table A-4 of the same document which addresses "issues with trip lengths for trips with origins or destinations outside the model" and other known trip issues is 13.1 for Grass Valley. Because the 13.1 value addresses trip issues, please update the standard to reflect this value.

**Agcy 8-30**

T-3) ***Table 4.12-8*** presents Project Trip Generation which includes automobiles and trucks but does not reflect passenger car equivalents (PCEs). To represent the impact that large trucks, buses and recreational vehicles have on traffic flow; trucks should be converted into PCEs. By their size alone, these vehicles occupy the same space as two or more passenger cars. In addition, the time it takes for them to accelerate and decelerate is also much longer than for passenger cars and varies depending on the type of vehicle and number of axles, particularly when considering the topography of the roads proposed for the haul route. Typical PCE factors are 1.5 for 2-axle trucks, 2.0 for 3-axle trucks and 3.0 for 4+-axle trucks. Please update trip generation to reflect truck PCEs.

**Agcy 8-31**

T-4) The issues addressed above need to be corrected in the Recirculated DEIR as the corrections will result in "Significant New Information" and are very likely to identify "A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance." per Section 15088.5 of the CEQA Guidelines.

**Agcy 8-32**

T-5) Page 4.12-35: The Existing Plus Approved Projects Conditions assumption fails to mention two approved projects in the City. The City approved Loma Rica Specific Plan amendments in 2019 and the Dorsey Marketplace project in 2020, well before

the release of the NOP. The City specifically noted these projects in its March 18, 2020, letter to Nevada County (copy attached), and again requests these projects to be included and taken into consideration.

T-6) There is no mention within the Cumulative Impacts chapter or any traffic analysis of the City's General Plan Circulation Element's planned new road on the Centennial site that would connect Bennett and Idaho-Maryland Road. The City has requested this issue be addressed in multiple letters to the County (copies attached). This road connection is highly likely to change the impact conclusions in Impact 4.12-9.

**Agcy 8-33**

**TIA COMMENTS**

TIA-1) ***Table 11*** of the TIA references daily trips (maximum and average) but does not indicate any truck to automobile equivalency (passenger car equivalent) factors to represent the trucks heavy vehicle effect on the roadway system. Truck traffic should be adjusted to PCEs (or otherwise fully represented) for analysis purposes.

**Agcy 8-34**

TIA-2) Please convert trucks to PCEs for LOS analysis OR update heavy vehicle factors. Heavy vehicle percentages in the LOS worksheets indicate 2% to 5% heavy vehicles (most are 2%). The ***appendix page labeled HCM 6th Signalized Intersection Summary MITIG8 Cumulative plus Project PM Peak 14: E. Bennett Rd/Brunswick Rd*** includes 2% Heavy Vehicle factor. However, Section XI (Acceleration on Grade) states that along Brunswick Road:

"Trucks currently account for about 6% of all traffic between SR 49 and SR 174, with the truck traffic increasing to about 9% between Whispering Pines Lane and E. Bennett Road. Trucks also account for about 8% of traffic along Whispering Pines Lane. "

**Agcy 8-35**

TIA-3) ***Tables 14A, 14B, 17A, 17B, 20A, 20B, 23A, 23B, 26A, 26B*** should be updated to reflect LOS analysis results with trucks fully represented.

**Agcy 8-36**

TIA-4) ***Tables 15A, 15B, 18A, 18B, 21A, 21B, 24A, 24B, 27A, 27B***: should be updated to reflect queuing analysis once trucks are fully represented. The TIA indicates "It is assumed that one additional vehicle (25') can store in the available left or right turn taper and this occurs at six locations". Overflow trucks may be significantly longer than 25' – please update to fully account for trucks.

**Agcy 8-37**

TIA-5) ***Section II.4 Findings/Results of the TIA*** indicates the Project generated VMT result is 14.7 for 2012 Base Year and 13.9 for 2035 Future Year. The TIA states that because 13.9 is less than the 18.6 average for Grass Valley, there is no VMT impact. However, VMT impacts are calculated on baseline conditions.

**Agcy 8-38**

Interpolation between 14.7 for 2012 and 13.9 for 2035 indicates the Project generated VMT would be 14.4 in 2020. The Grass Valley VMT/SP is 13.1 (a reduction of 14.3% results in a threshold of 11.2). The interpolated 2020 VMT/SP of 14.4 is more than the threshold and an impact is found. Please update the VMT findings.

**Agcy 8-39**

TIA-6) ***Maps such as Figure 4.12-1*** of the EIR / Figure 3 of the TIA should be corrected/adjusted (ramps are missing). For example, the off ramp at intersection 9 is missing, as is the on-ramp at intersection 5. In addition, Bennett Street is misspelled.

**Agcy 8-40**

TIA-7) For the ***intersection graphics such as Figure 4.12-2*** which make up the bulk of the traffic figures, please clarify the orientation of street intersections. For example, at intersection 20, it appears that Idaho Maryland Road (the east/west street) is listed first, but at intersection 21, Sutton Way (the north/south street) is listed first.

**CHAPTER 6: ALTERNATIVES ANALYSIS**

**Agcy 8-41**

ALT-1) The City understands that the formulation of alternatives must consider the applicant's goals and objectives for the project, but that consideration is limited as explained in the CEQA Guidelines Section 15126.6[b]:

"*Because an EIR must identify ways to mitigate or avoid the significant effects that a project may have on the environment (Public Resources Code Section 21002.1),* ***the discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly.*** (Emphasis added.)

In this case, the applicant's objective that the project's production rate should be 1,000 tons per day is a speculatively large number chosen by the applicant based upon estimates of recoverable gold that could be extracted over an 80-year time period. The County has no obligation to maximize production, and particularly if it can only be accomplished by decades of significant effects on the local community related to truck traffic generation, noise, air quality and greenhouse gas emissions, energy and fuel use, and a huge volume of disposed residual material. Because of this, the obvious environmentally superior alternative is the Reduced Throughput alternative with a production rate of 500 tons per day, which is still a very significant mining project, and would substantially lessen the significant effects of the project. The assumption that this alternative would result in an extension of the project's operations timeframe to "between 130-160 years" is unsubstantiated and is based entirely upon an assumption the mine can only be financially feasible if it

allows full development of the underground resources – an assumption for which there is no evidence in the record.

ALT-2) As noted in Project Description comments above, the applicant's objective that the project's permit term needs to be 80-years is extreme, and unprecedented in California. The County has no obligation to maximize the permit term due to the applicant's estimate of project feasibility recoverable gold to be extracted over 80-years. This is particularly so due to the nature and magnitude of significant effects on the local community related to truck traffic generation, noise, air quality and greenhouse gas emissions, energy and fuel use, and the volume of residual material to be generated and disposed. In this case, an obvious alternative to consider is a Reduced Throughput and Thirty-Year Permit alternative, which is still a very significant mining project, and would substantially lessen the long-term significant effects of the project.

**Agcy 8-42**

ALT-3) The assessment of alternatives 2 (Expansion of Brunswick Fill Pile) and 3 (Expansion of Centennial Fill Pile) is entirely predicated upon the assumption that the 1,000 tons per day objective needs to be attained, leading to conclusions that are inadequate and conclusory in nature. There is no support for the extraordinary expansion of fill piles. There is no need to expand the fill piles to the detriment of the benefits of the engineered fill if, as described elsewhere in the EIR, the materials can be used as backfill for the mine, and or transported "for use in local and regional construction markets" (DEIR, page 3-26).

**Agcy 8-43**

ALT-4) Page 6-3 aesthetics is listed as a less than significant impact, but on page 6-7, aesthetics is listed as a significant and unavoidable impact that cannot be fully mitigated, requiring the County to adopt a statement of overriding considerations if the project is to be approved.

**Agcy 8-44**

**CONCLUSIONS**

C-1) Collectively, the inadequacies identified in our review support our conclusion that rather than simply responding to comments, the County needs to substantially revise these analyses to repair the deficiencies, and prepare a Recirculated Draft EIR pursuant to CEQA Guidelines §15088.5, which states in part (applicable text in bold italics):

**Agcy 8-45**

**15088.5. RECIRCULATION OF AN EIR PRIOR TO CERTIFICATION**

(a) ***A lead agency is required to recirculate an EIR when significant new information is added to the EIR after public notice is given of the availability of the draft EIR for public review under Section 15087 but before certification.***

As used in this section, the term "information" can include changes in the project or environmental setting as well as additional data or other information. New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect (including a feasible project alternative) that the project's proponents have declined to implement. "Significant new information" requiring recirculation include, for example, a disclosure showing that:

(1) ***A new significant environmental impact would result from the project*** or from a new mitigation measure proposed to be implemented.

(2) ***A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance***.

(3) ***A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.***

(4) ***The draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded***. (Mountain Lion Coalition v. Fish and Game Com. (1989) 214 Cal.App.3d 1043)

[Note: Authority cited: Section 21083, Public Resources Code. Reference: Section 21092.1, Public Resources Code; *Laurel Heights Improvement Association v. Regents of the University of California* (1993) 6 Cal. 4th 1112.]

The issues addressed above need to be corrected in the Recirculated DEIR as the corrections will result in significant new information" per Section 15088.5 of the CEQA Guidelines, are likely to findings of a substantial increase in the severity of an environmental impact. The Recirculated DEIR should give serious consideration to a much shorter permit timeframe, reduced throughput, and with a condition of approval requiring an Adaptive Management Process under which the project gets reviewed periodically (every 10 years), with additional environmental compliance and mitigation requirements added to the permit conditions as needed. It should also consider treating the Centennial site backfill as a distinct project independent of the mining project.

We appreciate your serious consideration of our comments. As I am sure you are aware, this a very significant project that has the potential to affect the City of Grass Valley and the surrounding community in Nevada County through the end of this century. Please don't hesitate to call me if you have any questions or need additional information.

Sincerely.

Thomas Last

RE: Comments on the Traffic Impact Analysis for the Rise Grass Valley mining project.

Dear Mr. Kelley:

Thank you for the opportunity to provide comments on the draft report. The following comments raise several concerns with the traffic study. Since this project will have many direct impacts on City streets and intersections, the City strongly encourages the County to consider and require these comments to be properly addressed.

1. In general, the report is extensive, and the City would like to have had more time to evaluate the report in more detail.
2. Traffic Index (TI) analysis for Whispering Pines requires further explanation. Even over a 5-year period a four-axle truck equates to 1470 ESAL according to the KDA chart. If there are 114 (4 axle) trucks per day this would be 167,580 ESAL which should easily move the TI up at least 0.5 Regardless Whispering Pines Rd was not constructed to handle heavy industrial traffic, let alone act as a haul route, and is nearing the end of its useful life already. Putting 114 heavily loaded trucks a day on this road will cause it to fail well before a 5-year period. This project needs to be conditioned to enter into an agreement with the City to ensure long-term pavement maintenance occurs on all haul road streets and to cover all costs associated with upgrading from the current TI on Whispering Pined Lane to an appropriate TI.
3. TI analysis for Brunswick requires further explanation. How can one section (E Bennett to Whispering Pines) show an increase, but not the other (Whispering Pines to SR49) that is already in a lower TI? How can 5880 ESAL x 114 trucks = 670,320 ESAL not increase the TI to at least the next step? As we have noted in previous letters, the applicant will be required to enter into a maintenance agreement with the City to pay for roadway maintenance and improvements and shall cover all costs associated with upgrading from the current TI to an appropriate TI.
4. LOS calculations are not consistent with any recently accepted traffic studies (Dorsey Marketplace or Loma Rica Specific Plan, specifically). The majority of intersections analyzed in the Rise Mine ITA are already failing or already identified to be failing under previous Existing plus Approved Projects scenarios.
5. The 3:30-4:30 time is not a typical study period included in the Grass Valley Model. Regardless, this period falls within PM peak hours (4-6 p.m.) so PM peak numbers must be utilized.

6. For all intersections that are expected to operate at an unacceptable LOS, the project shall either, pay their fair share contribution if the project is in the GVTIF, or shall construct the improvements and enter into a reimbursement agreement.
7. The City concurs with TJKM's Attachment 2: Traffic Mitigation Measures summary table and disagrees with nearly all responses that said intersections do not require mitigation. As noted, the majority of intersections are already failing under Cumulative conditions, thus the recommended mitigations listed will be required.
8. As it pertains to cumulative impacts, the study did not include approved projects that were approved by the City at the time the Notice of Preparation was routed, as required by the California Environmental Quality Act. Two specific projects, Loma Rica Specific Plan and Dorsey Marketplace need to be included in any cumulative analysis. Both of the traffic studies for those projects, conclude much different LOS impacts to multiple intersections (multiple cumulative D, E, and F intersections) than what is concluded in the mine project's cumulative impacts. This is a flaw in the study that needs to be resolved.
9. As it pertains to VMT methodology, the City has two concerns:
    a. Though heavy truck traffic is not included in the analysis and there is discussion as to why not, the City disagrees with not including this in the VMT. Heavy truck traffic is a key component to the project itself and without it the project cannot succeed. It is a critical and necessary part of the project and in a sense this is similar to a sand and gravel trucking operation, and therefore, cannot be discounted. If heavy truck traffic were not part of this project, the City would agree it does not need to be included.
    b. The City also disagrees with the VMT applied to employees. There are very limited housing opportunities within 20–30-mile radius of the mine site to accommodate the number of expected employees. The City strongly believes the 14.8 mile average is unrealistic based on current housing conditions in the region and the study needs to better explain the rationale for this number or provide a more reasonable and realistic assumption for employee VMT.
10. Sight distance calculations for new driveway shall be submitted for further review.

If you have any questions, please call me at 274-4711 or email at toml@cityofgrassvalley.com.

Sincerely,

Thomas Last

RE: NOP for the CUP and Reclamation Plan for the Rise Grass Valley mining project.

Dear Mr. Kelley:

Though the City is perplexed why the NOP has been released when the application is still incomplete, we offer the following comments in response to the NOP. Furthermore, since the application is incomplete and there is a possibility that the project description could change, the City reserves the right to provide additional comments on the scope of the EIR once the application is complete.

1. Since December 2019, the City has provided a consistent request on multiple occasions to the applicant that we expect them submit a conceptual application to the City so we can provide a formal response on the annexation/lead agency question. This approach is supported within the City/County Tax Share Agreement, the City/County MOU on joint land use planning in the sphere of influence, and by County General Plan Policy 1.8.4. To date, the applicant has been unwilling to follow the City's and County's process for review of projects within the City Sphere of Influence.
2. The EIR must address service impacts on the City fire and police services. Due to mutual aid agreements with respective agencies and because of the location of City facilities, this project will have a significant impact on both police and fire services. It is likely that some of the buildings will need to rely on the City's fire apparatus (ladder truck) and the project needs to ensure access to those structures.
3. The EIR must address noise and vibration issues caused by underground blasting and above ground activities that could impact existing high-tech companies in the Whispering Pines area.
4. The EIR must adequately address the treatment of stormwater runoff and mine dewatering that leaves the site and eventually travels into the City limits.
5. Since the project proposes to dewater the mine and place it into the South Fork of Wolf Creek, the EIR must address the flooding and storm drain system issues associated with the increase in water flows into this creek and on the City infrastructure. There are several areas in the City that already experience flooding issues and adding more water into this creek must be addressed.

6. The EIR must address the traffic impacts to City roads. There are multiple intersections and road segments that will be impacted. Additionally, the EIR must address site distance issues and other safety concerns with the proposed haul route.
7. The City's General Plan shows a connecting road between Bennett and Idaho-Maryland Roads. The EIR needs to address this issue re the planning and potential realignment of Centennial Road with Springhill Road.
8. The City has concerns with the proposed truck routes to the Centennial Industrial site and impacts on City roads. The City will require a tonnage fee or other mechanism to be placed on the project to ensure proper long-term maintenance. The transport of material 16 hours a day 7 days a week will conflict with City noise limits for typical construction projects. The residents along Brunswick road could be severely impacted by the constant noise of trucks.
9. The EIR needs to address the decrease in water flows into Wolf Creek from the shaft along Idaho-Maryland Road created by dewatering.

If you have any questions, please call me at 274-4711 or email at toml@cityofgrassvalley.com.

Sincerely,

Thomas Last
Community Development Director

Nevada City, CA 95959

RE: Initial comments on CUP and Reclamation Plan for the Rise Grass Valley mining project.

Dear Mr. Kelley:

The following represents the City's preliminary comments and concerns on the above project. This is not to be considered an exhaustive review by the City. It also includes several recommendations I noted at the December 16, 2019, meeting at the County offices.

1. Though staff indicated the City is unlikely to be interested in annexation and processing of the application, the City is requesting the County and applicant follow past practice and have the applicant submit a conceptual application to the City so we can provide a formal response. As discussed at the meeting, staff would then submit this to the City Council to get its direction on processing the application due to the magnitude and complexity of this project.
2. If it is not processed in the City, the City requests the County and City enter into a Memorandum of Understanding (MOU). Since this project has the potential to create several significant impacts on the City, the purpose of the MOU would be to set up procedures that ensure impacts of the project on the City will be fully incorporated into the project. Some of the items raised at the meeting included impacts on: a) fire and police services; b) noise and vibration issues on existing high-tech companies in the Whispering Pines area; c) water treatment; impacts to City roads; d) the City's General Plan's that shows a connecting road between Bennett and Idaho-Maryland Roads - planning for and setting aside land for a realignment of Centennial Road with Springhill Road; e) storm water requirements (City system capacity, treatment standards, etc.) that meet City standards since the water will flow into the City.
3. I discussed the need for the applicant to pay the City to obtain assistance with its review of the project. The City understands the concern with duplicating consultants with the City and County, but we do not have staff resources to provide proper attention and review of the project.
4. As discussed at the meeting, the City hired a mining consultant, geochemist, and other specialized consultants beyond the EIR consultant when it processed the proposed Idaho-Maryland Mine project in 2005.

5. It is likely that some of the buildings will need to rely on the City's fire apparatus (ladder truck) and the project needs to ensure access to those structures.
6. The City has concerns with the proposed truck routes to the Centennial Industrial site and impacts on City roads. The City will require a tonnage fee to be placed on the project to ensure proper long-term maintenance. The transport of material 16 hours a day 7 days a week will conflict with City noise limits for typical construction projects. The residents along Brunswick road could be severely impacted by the constant noise of trucks.
7. As the design of the proposed fill site moves forward, the City would request the applicant work with the City on setting aside land for the Wolf Creek Trail for the property along Idaho-Maryland Road in addition to designing the fill to accommodate a realigned road noted above.
8. Since the applicant proposes to dewater the mine and place it into the South Fork of Wolf Creek, the EIR must address the flooding and storm drain system issues associated with the increase in water flows into this creek. There are several areas in town that already experience flooding issues and adding more water into this creek must be addressed.
9. Need to address the decrease in water flows into Wolf Creek from the shaft along Idaho-Maryland Road created by dewatering.
10. Also, the City has a Master Environmental Assessment, Draft EIR and multiple technical studies from the 2005 mine project we can share with the County. Though this project proposes the operations occurring on the New Brunswick site, our records can provide some insight on the issues and community concerns.

If you have any questions, please call me at 274-4711 or email at toml@cityofgrassvalley.com.

Sincerely,

Thomas Last
Community Development Director

**TECHNICAL REVIEW TEAM RESUMES**

**Jeffrey G. Harvey, Ph.D.**
**Principal & Senior Scientist**
**Harvey Consulting Group**
(916) 799-6065 (direct)
Harvey-Jeff@sbcglobal.net

***Summary of Qualifications***

Harvey Consulting Group provides environmental compliance and project development support services to clients throughout California for water resources, energy/transmission, mining and reclamation, and land development projects. Our primary services include project management and planning, public involvement, environmental impact assessment, policy development, and regulatory permitting. We are dedicated to providing outstanding client service, and technical and management expertise for complex and controversial projects.

The firm's principal, Dr. Jeffrey G. Harvey, has worked as an environmental consultant in California for more than 30 years. He has expertise in requirements of the California Environmental Quality Act (CEQA), National Environmental Policy Act (NEPA), and related laws and regulations pertaining to water supply, water quality, land use planning, air quality, biological resources, cultural and historic resources, and natural resources conservation and management. He has organized and managed more than 300 projects, leading multi-disciplinary teams of scientists, engineers, lawyers, economists, and planners. Projects have included environmental assessments and permitting for water and energy development, mining, policy analysis of water resources and energy systems management, public infrastructure projects, industrial development and mining. As Senior Project Manager, he is responsible for client liaison, team coordination and task assignments, and for keeping projects on schedule and within budget. He also performs primary quality assurance / quality control functions for the team.

He has worked on western water, energy and related natural resources policy issues for most of his career, including water development, management, and planning, and analyses of land and agricultural water use practices and conservation, and power plant and hydroelectric power development. He worked on the San Joaquin Valley Drainage Program conducting resource management and policy studies of irrigated agriculture for the purpose of reducing toxic levels of selenium in drainage water, and to improve water use efficiency and water supply through improved on-farm water management.

Special emphasis has been placed on client representation, active coordination with agency staff and government decision-makers, and effective presentations and public testimony. In managing planning and document preparation, Dr. Harvey has streamlined the reporting and regulatory process through

development of detailed project objectives and focused identification of issues; effective consultation and liaison with regulatory agency staff and the applicant's representatives; and preparation of concise, organized, and readable reports. He has developed cost-effective mitigation strategies to resolve regulatory issues without impairing project goals and has prepared long term monitoring criteria to measure successful project implementation.

## Education

**Ph.D. in Geography**
University of California, Los Angeles. Environmental Law and Policy, Hydrology and Water Resources, Natural Resources Management, and Impact Assessment.

**M.A. in Geography**
California State University, Chico. Environmental Planning, Water Resources Development, and Impact Analysis.

**B.A. in Geography**
California State University, Chico. Physical Geography; minor concentrations in Anthropology and Geology.

## Professional Experience

2005 to present: *Harvey Consulting Group (HCG)*
**Principal and Senior Scientist**, private consulting practice providing professional services to local, state, and federal agencies, and private developers for water, power, mining and industrial land development projects.

1994 to 2005: *Greystone Environmental Consultants*
**California General Manager**, responsible for management of California offices in Sacramento and San Diego (for a company headquartered in Denver, Colorado); administrative and personnel management, business development, project management, client and public agency liaison.

1985 to 1994: *Research Associates*
**Principal and Project Manager**, private consulting practice providing professional services to local, state, and federal agencies, nonprofit environmental groups, and private developers.

## Representative Mining Projects

The projects listed below include project management, regulatory permitting and environmental assessment spanning more than 30 years. References available for all projects within the past 10 years.

**City of Grass Valley, Idaho-Maryland Mine Project DEIR**

Project Manager as a subconsultant to ESA Associates for preparation of the Draft EIR for the proposed Idaho-Maryland Mine project. This multi-stage environmental review process included extensive community involvement and scoping. The proposal included reopening the historic Idaho-Maryland Mine to develop industrial and precious mineral deposits into gold and stone ceramic products. The project comprised three properties that encompassed a total of 138-acres of land. Project actions included dewatering and rehabilitating the historic Idaho-Maryland Mine workings, conducting underground resource exploration and development, developing the industrial mineral and gold ore deposits, processing mineral deposits to produce gold and manufactured stone and ceramic building products, operation and maintenance of these facilities, and performing reclamation activities at the project sites at the conclusion of the project. Primary responsibilities included scoping, public involvement and agency coordination, technical analyses of geology, hydrogeology, and geochemistry, and QA/QC of draft document sections. Project applicant withdrew their application and the project concluded at the Draft EIR stage.

**Olive Pit Mining & Reclamation Operations and Long-Term Reuse Project**

Environmental Impact Report to assess the extraction of all economically recoverable mineral resources from the 190-acre Olive Pit, and reclamation of the eastern 32 acres by filling to street level for future urban development. In partnership with the City of Irwindale, United Rock Products ("United Rock" or "Applicant") will resume mining operations at the Olive Pit and will reclaim the site concurrent with mining. The Proposed Project is expected to yield a minimum of 32-million tons of recoverable aggregate reserves that meet the quality standards of applicable California governmental agencies. Average production is anticipated to be 1 million tons of aggregate per year beginning in 2015. Mining will occur for a period of approximately 32 years with concurrent filling operations for reclamation commencing in the first of two phases. The remainder of the property will be reclaimed for the potential end land use of storm water retention and groundwater recharge, and/or flood control facility, and/or open space recreational land uses. Mining activities will utilize both dry and wet mining operations; and are subject to the City's guidelines for slope stability and public safety. Key issues involved traffic, noise, land use conflicts, air quality and biological resources.

**United Rock Products Quarry and Reclamation Plan EIR**

Senior Project Manager for preparation of an EIR for a quarry expansion project that involved 3 quarry locations, reclamation activities and post - reclamation land development projects. Key issues for the project included air quality related emissions of fugitive dust, geotechnical and slope concerns, groundwater exposure and contamination and underwater dredge activities. The impact analysis focused on current and future activities to the approximate horizon year of 2100 due to the protracted rate of

quarry reclamation activities. This was a fast-track project completed in five months after another consulting firm had failed to perform, leaving the City in a schedule bind and facing litigation. The EIR was successfully completed on the accelerated schedule, and litigation was avoided.

**Vulcan Materials Company Mining and Reclamation Plan EIR**
Project Manager for preparation of an EIR for a quarry expansion and reclamation project that included deepening and extending the life of two (2) aggregate quarries along with concurrent reclamation. The EIR included environmental review and analysis of an existing Class "U" Inert Debris Engineered Fill landfill; for both current operations and reclamation activities. The EIR assessed a programmatic evaluation of post-reclamation land uses for all three (3) project sites (Durbin Quarry, Reliance I Quarry, and Reliance II Landfill). Key issues for the project included fugitive dust, geotechnical and slope stability, groundwater exposure, contamination and underwater dredge activities, traffic, circulation, and roadway impacts, and post-reclamation land use planning.

**Vulcan Materials Co. Mining & Reclamation Plan EIR Addenda 1, 2 &3**
Project Manager for CEQA and SMARA compliance. These addendum documents to the Vulcan Materials Company Mining & Reclamation FEIR were prepared individually over a period of three years to evaluate proposed minor modifications to the Conditional Use Permit. Evaluations included the requested to modify conditions of approval at the Durbin and Reliance I Quarry sites, changing the hours of operation from 24 hours per day six days per week to 24 hours per day seven days per week, and to include the entire Reliance mine site under one reclamation plan with one State mine identification number (this mine is divided by the municipal boundaries of the cities of Irwindale and Azusa). Key issues included air quality, noise, and traffic/circulation. In each case, the proposed actions were concluded to be within the scope of the Vulcan FEIR and fulfilled the CEQA review necessary for an Addendum to an EIR.

**Nu-Way Live Oak Inert Landfill Mitigated Negative Declaration**
Project Manager for the preparation of an Initial Study and Mitigated Negative Declaration (MND) to allow for the closure and final reclamation of the Nu-Way Live Oak Inert Landfill. The Live Oak landfill is currently being reclaimed with inert material and was formerly operated as an aggregate quarry. A previously certified EIR for this landfill indicated that landfill reclamation would continue until street grade level was achieved. The operator of the landfill submitted a request to the City of Irwindale to allow for final reclamation, grading and closure to occur now which will result in site reclamation occurring to a level below that previously expected. The focus of the CEQA MND was to evaluate the difference in the revised project description and the resultant net environmental effect of ceasing landfilling operations early and not achieving site consistency with the surrounding street grade level. Key issues for this project were hydrology and drainage, geology and soils, water quality, and air quality.

**Mining Impact and Reclamation Study**
Impact Analysis, Environmental Planning and Policy Development. Project Manager for comprehensive analyses of mining activities within jurisdiction of the City of Irwindale, including evaluation of environmental and economic conditions, and options for reclamation and long-term economic development. A comprehensive two-volume report was prepared including analysis of existing mining operations for compliance with the state Surface Mining and Reclamation Act (SMARA), physical and environmental effects of mining within the City, and development of reclamation policies to guide long-term land use planning and economic development. The study covered 14 open-pit mines ranging from 80 to 500 acres in surface area, and minimum 100-feet to more than 200-feet deep. Of the 14 total sites, seven are active mines, four are implementing landfill reclamation, and three are inactive mines. Follow-up tasks have involved support in proceedings with the State Mining and Geology Board, assistance in development and promotion of legislative proposals to amend SMARA, technical review of reclamation plans and related environmental documents, and development of a revised financial assurances program for the City.

**Mining Assessment for the City of Azusa**
Senior Project Manager for a project involving an assessment of the existing Vulcan Materials mining operations to assist the City of Azusa in determining the nature and extent of existing minerals resource extraction entitlements under CEQA and SMARA and to identify required additional entitlements necessary to allow for an expansion of operations to include an 80-acre parcel contiguous to the existing 270-acre mine. Analyses included a market assessment of existing materials mined by Vulcan, a geologic assessment to determine future resource extraction value potential for the proposed new 80-acre mine and future reclamation options and an analysis of current measurement and reporting methodologies. Developed an implementation strategy to improve reclamation planning and identify opportunities and actions for ensuring Vulcan complies with all applicable City plans, policies and ordinances, SMARA and CEQA requirements.

**Yuba County, Hallwood Aggregate Mine**
Project Manager for preparation of a *Surface Mining Reclamation Plan* for an aggregate mine operating in former gold mine dredger tailings within the Yuba River corridor in Yuba County. Analyses also included impact assessment of the current aggregate mining and processing operations, hot plant and off-site transportation. The reclamation included multiple phases in sequence with planned mine expansion activities designed to be implemented concurrent with ongoing mining.

RCH GROUP
planning & environmental consulting

## Paul Miller

Managing Principal, Environmental Services

Paul is an environmental professional with more than 35 years of experience in providing services and products to government agencies and private sector corporations. His technical areas of expertise include CEQA project management and technical analyses in the areas of air quality, greenhouse gas emissions, noise, integrated waste management, energy, and hazardous materials. With a broad range of environmental skills, he has applied his background since 1986 to CEQA and NEPA and has been integral in the preparation of over 500 CEQA/NEPA environmental documents, including project manager for more than 20 major EIRs. He has been the project manager or a key team leader for five state agencies (California Public Utilities Commission (CPUC), California Energy Commission (CEC), CalRecycle, the former California Integrated Waste Management Board, and the State Water Resources Board, Central Valley Region) on projects of statewide importance. He was the senior air quality and noise reviewer for CEQA documents at ESA for almost 20 years. Since the 1989 Paul has been involved in dozens of projects that that analyze the high-volume trucking of materials to or from industrial sites (landfills, composting facilities, and mines).

CEQA/NEPA Project Experience:

- **Quarrying/Mining CEQA/NEPA documents:** Idaho-Maryland Mine EIR 2007-2008 (City of Grass Valley), Olive Pit Mine EIR and Kincaid Pit IS/MND (City of Irwindale), Permanente Quarry Reclamation Plan Amendment EIR (Santa Clara County), R&J Aggregate Mine EIR and La Vista Quarry (Alameda County), Roblar Road Quarry EIR and Canyon Rock Quarry Expansion EIR (Sonoma County), San Rafael Rock Quarry EIR and San Rafael Rock Quarry Extension Application Supplemental EIR (Marin County), Vernalis Quarry EIR (San Joaquin County).
- **Project Manager and Senior Air Quality Reviewer of Energy Projects for California Public Utilities Commission (CPUC) CEQA documents:** Pacific Gas and Electric Co. (PG&E) Divestiture EIR for Hydroelectric System Divestiture EIR; PG&E Divestiture EIRs to sell Morrow Bay, Moss Landing, Oakland, Potrero, Pittsburg, and Contra Costa Power Plants; San Diego Gas and Electric Company's (SDG&E's) Power Plant Divestiture Mitigated Negative Declaration; Mitigated Negative Dec (MND) to divest Southern California Edison Company's power plants.
- **Landfill CEQA documents:** Yolo County Central Landfill Permit Revisions EIRs (2007 and 2021) , Forward Landfill Expansion EIR, Austin Road Landfill Expansion EIR; Altamont Landfill and Resource Recovery Facility Expansion EIR; Time Extension of Importation of Contra Costa County Waste to the Altamont Landfill EIR; Altamont Landfill Reclassification (Class II) EIR; West Contra Costa Landfill Closure CEQA Technical Assistance; Ostrom Road Landfill Permit Modifications (Class II) EIR; Eureka County Nevada Solid Waste Management NEPA EAs; Bakersfield City Sanitary Landfill; Closure/Post-Closure Maintenance Plans EIR; San Leandro Landfill Gas Collection and Flaring System Mitigated Negative Declaration; New Jamestown Landfill EIR; Sutter County Ash Disposal Site EIR; Ukiah Landfill Permit Revision Supplemental EIR; Ukiah Landfill Closure EIR (2020), Marsh Canyon Landfill EIR.
- **Senior Air Quality and Greenhouse Gas Reviewer:** Honda Port of Entry EIR (Port of Richmond), Union Pacific Railroad Modernization EIR (Lathrop, CA), Eagle Mountain Pumped Storage Hydroelectric EIR and EIS (Mohave Desert), Oasis Shopping Center Master EIR (Redding, CA), San

Rafael Rock Quarry EIRs, La Vista Quarry EIR (Alameda County), Novato Sanitary District Master Plan EIR, SAFCA Mayhew Levee Replacement Project Peer Review.

- **Senior Noise Analyst and Reviewer**: Mr. Miller has been collecting high-quality noise measurements since 1988. He specializes in collecting baseline environmental noise data and analyzing the potential noise impacts of proposed projects in CEQA and NEPA documents. RCH uses a noise data collection and processing system that he has been continually modifying and enhancing the processes for data accuracy and cost efficiency. The combined hardware/software system uses higher-capacity batteries, portable computers to download data, and customized software to automatically plot daily noise data showing relevant standards and noise monitoring locations.
- **Anaerobic Digestion CEQA documents:** CalRecycle (formerly the California Integrated Waste Management Board), Statewide Program EIR for Anaerobic Digestion Facilities; Central Valley Regional Water Quality Control Board (Central Valley Water Board) - Dairy Manure Digester and Manure Co-digester Program EIR; Blue Line Materials Recovery Facility (MRF), Transfer Station Anaerobic Digester with Compressed Natural Gas (CNG) Production MND, and Hitachi Zosen Inova Anaerobic Digester (San Luis Obispo County, public meeting EIR air quality presentations).
- **Material Recovery Facility CEQA documents:** Irwindale Material Recovery Facility EIR, South San Francisco Scavenger Company Materials Recovery Facility EIR; West Contra Costa County Integrated Resource Recovery Facility EIR; Sanitary Fill Solid Waste Transfer Station and Household Hazardous Waste Facility EIR; Yuba-Sutter Disposal Inc. Transfer Station and Compost MND; Stockton Scavenger Transfer Station Focused EIR; City of Fremont Transfer Station/MRF/Composting Facility EIR.

**Education**
1977 Master of Science (Zoology and Entomology)
Colorado State University – Fort Collins, Colorado
1974 BA Zoology, Miami University – Oxford, Ohio

**Professional Certifications and Affiliations**
- California Air Resources Board -Accredited GHG Verifier of Emissions Data Reports for Mandatory Reporting
- Member, Association of Environmental Professionals (AEP)
- Board Member since 2010, Air and Waste Management Association, Mother Lode Chapter of Golden West Section

**25+ Years Consulting Experience**
- Environmental Science Associates (ESA)

## Dan Jones

Senior Associate /Air Quality & Noise Analyst

Dan Jones is an environmental professional with over eight years of experience in providing environmental services and products to government agencies and private sector corporations. Dan's technical areas of expertise include CEQA project management and document preparation and technical analyses in the areas of air quality, greenhouse gases/climate change, energy, and noise. Dan has been integral in the preparation of over 300 CEQA documents and technical studies supporting such documents. Dan's technical noise experience includes short-term and long-term noise monitoring and noise modeling with the Federal Highway Administration's Roadway Construction Noise Model and Highway Traffic Noise Prediction Model. Dan is proficient in a variety of air emissions models including California Air Pollution Control Officers Association's CalEEMod, California Air Resource Board's EMFAC and OFFROAD, and Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model.

CEQA/NEPA Project Experience:

- **Mining Projects:** Olive Pit Mine and Reclamation Project EIR, R&J Aggregate Mines EIR, Olive Pit Mine and Reclamation Project EIR Addendum, and Irwindale Kincaid Pit Remediation and Reclamation Project, San Rafael Rock Quarry Extension Application Supplemental EIR, and Salton Sea Lithium Project EIR.

- **Water Conveyance/Infrastructure Projects:** East Bay Municipal Utility District (EBMUD) Sobrante Water Treatment Plant EIR, Buena Outfall Force Main Phase III IS/MND, Oasis Irrigation System Expansion Project EIR, Carmel River Floodplain Restoration and Environmental Enhancement (CRFREE) Mitigation Pipeline Underground Project IS/MND, The People's Moss Landing Water Desalination Project EIR, Central Amador Water Project Pioneer Water Rehabilitation Project IS/MND, Cuesta Heights Water Storage and Distribution Improvements Project IS/MND, Alameda Creek Levee Improvement IS/MND, Christian Valley Park Community Service District Water Storage Tank Project IS/MND, Modesto RD 2091 Levee Air Quality Analysis, Santa Venetia Timber Reinforced Berm Improvement Project, and San Joaquin Mormon Slough Levee Air Quality Analysis.

- **Waste Management Projects:** Glenn County Solid Waste Conversion Facility EIR, Blue Line Biogenic CNG Facility CEQA Addendum, Recology Vallejo Permit Revisions IS/MND, Valley Springs Recycling Center IS/MND, Irwindale Materials Recovery Facility/Transfer Station EIR, Sierra Waste Transfer Station Permitting, Forward Landfill SEIR, North Richmond Chip & Grind GHG Analysis, San Luis Obispo Anaerobic Digester IS/MND, Fair Deal Recycling Facility IS/MND & Transfer Processing Report, Ukiah Landfill Closure EIR, San Luis Obispo Anaerobic Digester Odor Impact Minimization Plan, Irwindale Materials Recovery Facility/Transfer Station EIR Addendum, San Luis Obispo Anaerobic Digester Authority to Construct Permit, Stage Gulch Organics Compost Facility EIR, and Yolo County Central Landfill (YCCL) Permit Revisions EIR.

- **Energy Projects:** Castor Solar Noise Study, California Public Utilities Commission Fulton-Fitch Mountain Reconductoring Project, California Public Utilities Commission Central Valley Power Connect 230 kV Project, California Public Utilities Commission Riverside Transmission Reliability Project, San Diego Gas & Electric TL 695, TL 6971 Reconductoring Project and Santa Paula Battery Energy Storage System IS/MND, PG&E Wheeler Ridge Junction Project, Gemini Solar EIS, Burney Bioenergy Facility Air Quality Analysis, and Salton Sea Geothermal Project.

- **Restoration/Recreational Projects:** Rockville Trails IS/MND, High Plains Shooting Sports Center Noise Analysis, Putah Creek Restoration Projects Program EIR, Lower Putah Creek Restoration Project IS/MND, Lake Chabot Campus Modernization IS/MND, Phillips 66 Company Line 200 Release Remediation Project IS/MND, Bay Point Restoration and Public Access IS/MND, University of California Santa Barbara Sea Wall IS/MND, Black Diamond Mines Preserve EIR, North Bay Wetland Mitigation Bank Air Quality and GHG analysis.

- **Residential/Commercial/Industrial Development Projects:** Alameda County Monte Vista Memorial Gardens EIR, Marin County Alta Way IS/MND, San Marin High School Turf Field Categorical Exemption, San Marin High School Expansion IS/MND, Novato High School Expansion IS/MND, Colfax Maidu Village Commercial Center IS/MND, City of Sacramento Fruitridge Shopping Center Redevelopment IS/MND, City of Sacramento River Oaks (The Cove) EIR Addendum, Colfax Corporation Yard and RV/Boat Storage IS/MND, Colfax Auburn Street Hotel IS/MND, Colfax Sierra Oaks Estates Residential Development IS/MND, Shasta 10 Noise/AQ/CAP Consistency Analysis, Morgan Knolls Subdivision IS/MND, Rocklin Meadows Subdivision AQ/GHG Analysis, Wildcat Subdivision AQ/GHG Analysis, Winding Creek Subdivision Noise Analysis, Rancho Vista Subdivision AQ Analysis, Riolo Vineyards Specific Plan IS/MND, Nevin Avenue Apartments IS/MND, Calistoga Subdivision Noise/AQ/CAP Consistency Analysis, Residences at Railway AQ/GHG Analysis, Centennial Towers North Tower AQ/GHG/HRA Analysis, 488 Linden Avenue AQ/HRA Analysis, 255 Cypress Avenue AQ/HRA Analysis, Centennial Towers R&D Project AQ/GHG/HRA Analysis, Whitehawk I & Whitehawk II AQ/GHG Analysis, Viri Estates Skilled Nursing Facility IS/MND, Alviso Village AQ/GHG/HRA Analysis, Lakeside Fire Protection District IS/MND, Green Island Road Wine Warehouse AQ/GHG/HRA Analysis, Pruneyard Shopping Center AQ/GHG/HRA Analysis, Richmond Terminal 3 Timber Export Facility IS/MND, 901 Larch Avenue IS/MND, 52 Franklin Avenue IS/MND, UCSF Research Building and Parking Garage Expansion EIR, 150 Airport Blvd IS/MND, Oak Knoll Mixed Use Community Plan EIR, Lincoln Northeast Quad Specific Plan HRA, Oakland T12 Office Tower, Sonora Food Service Building IS/MND, Osgood Heights IS/MND, 550 Gateway Blvd Hotel IS/MND, Justin Vineyards & Winery Permit Application, Sunnyvale Atria on El Camino Real AQ/GHG/HRA Analysis, Quarry Place Mixed Use Development AQ/GHG/Noise Analysis, First and Campbell AQ Analysis, Roseville Junction Crossing Noise Analysis, William Jenkins Health Center Noise Analysis, John Henry High School AQ/Noise Peer Review, Sierra Oaks Estates and Village Oaks IS/MND, The Parkway Apartments IS/MND, Cal Expo Rock & Brews CEQA Categorical Exemption, Solana Beach Skyline Elementary School Reconstruction Peer Review, Folsom Bidwell Pointe CEQA Infill Exemption, Granite Bay Joe Rodgers Subdivision AQ/GHG/Noise Analysis, Monarch Vista Apartments IS/MND, Double S Ranch Subdivision AQ/GHG Analysis, Vista Self Storage IS/ND, Novato High School Turf Field Categorical Exemption, Colfax Sierra Oaks Estates and Village Oaks CEQA Addendum, Bayview Health Risk Assessment, The Oaks Assisted Living CEQA Addendum, Dutton Meadows CEQA Addendum, Rocklin Tractor Supply Company AQ/GHG Analysis, Yolo County Haykingdom Expansion IS/MND, and Yolo County Cold Storage IS/MND.

Member, Association of Environmental Professionals

**JOHN KAIN**, AICP
PRINCIPAL, URBAN CROSSROADS, INC.
jkain@urbanxroads.com

## BACKGROUND

Founding partner John Kain is a transportation planner who is particularly skilled at the integration of traffic projections with meaningful designs that improve elements of the built environment and expand our mobility choices. Mr. Kain's 40 years of professional experience stretches through the spectrum of transportation domains. These include plans for new communities, City General Plan mobility/circulation elements, traffic impact analyses, regional and local funding programs, transit station area designs, accommodations for pedestrians and bicyclists, shared parking studies, roundabout scaled concept plans, and implementation of "complete streets" strategies. Mr. Kain is a Fellow in the Institute of Transportation Engineers.

URBAN CROSSROADS

# MARLIE WHITEMAN, P.E.

SENIOR ASSOCIATE, URBAN CROSSROADS, INC.
mwhiteman@urbanxroads.com

## BACKGROUND

Senior Associate Marlie Whiteman, P.E., is a transportation engineer with over 20 years of full time consulting experience in travel demand forecasting, traffic impact analysis, and mobility assessments. She is a recognized transportation modeling expert, with strengths in model data development, consistency, validation, preparation of future forecasts, post-processing, as well as circulation planning, parking evaluations and access studies. Ms. Whiteman's hands-on capabilities include the use of various modeling software packages, such as TransCAD, Cube, and Tranplan. She earned a Bachelor of Science degree in Civil Engineering from the University of California, Irvine.

## EDUCATION

**B.S. – Civil Engineering**
University of California, Irvine • 1996

## REGISTRATIONS

**PE** Registered Professional Traffic Engineer – TR 2186 • 2003

## AFFILIATIONS

**OCTEC** Orange County Traffic Engineering Council

**APA** American Planning Association

**ITE** Institute of Transportation Engineers

## SELECTED ACCOMPLISHMENTS

AEP Environmental Analysis Merit Award • 2018
(CV Link Multi-Modal Transportation Project)

APA National Planning Achievement Award and Orange County Award of Merit • 2008

URBAN CROSSROADS

## AGENCY LETTER 8: THOMAS LAST, GRASS VALLEY COMMUNITY DEVELOPMETN DEPARTMENT

### Response to Comment Agcy 8-1

This comment is introductory in nature and provides general concerns regarding the project and its associated EIR. The commenter's specific assertions are addressed in the responses below.

### Response to Comment Agcy 8-2

Nevada County General Plan Policy 17.7 states:

> *Use permit time limits for each project shall be established on a case-by-case basis. Time limits shall be based on the reasonably expected life of the mining operation and potential conflicts with future neighboring land uses. Each project shall have a periodic review for compliance with the use permit by the Planning Agency. In no case shall such review time period exceed five years. Said review shall be funded by the applicant.*

In this case, the applicant's requested 80-year permit timeframe is based on the historic production and potential for extension of the underground mineral resources to depth and the high level of capital investment needed to make the mine operational.

### Response to Comment Agcy 8-3

The commenter proposes a reduced scale version of the project, whereby the 1,000 tons per day goal is reduced to a cap of 500 tons per day or less and no nighttime hauling. It is unclear what the commenter considers as nighttime activities. For clarification, the DEIR notes that trucking of engineered fill to the Centennial Industrial Site and local construction markets via SR 49 is scheduled at 16 hours per day from 6AM to 10PM (e.g., DEIR Table 3-7 and page 6-14). With an average of 50 trucks per day this is approximately 3 trucks per hour, and with a maximum of 100 trucks per day, this is approximately 6 trucks per hour.

The commenter's recommendation for a reduced project was evaluated as an alternative in Chapter of the DEIR - Alternative 4, Reduced Throughput. Alternative 4 was found to meet most of the project's objectives but would not meet Objectives 1 and 7 due to the difficultly in financing a project of this scale with lower throughput and the reduced number of employees. Further, this alternative would not reduce any of the project's significant impacts below the threshold of significance, with the possible exception of some intersection traffic impacts.

### Response to Comment Agcy 8-4

The hours of operations for various activities are shown in Table 3-7 of the DEIR. Offsite hauling of engineered fill (which would include transport and dumping of the load) would take place from 6:00 AM to 10:00 PM 7 days a week. Placement, grading, and compaction of engineered fill would take place from 7:00 AM-3:30 PM Monday-Friday. The offsite hauling activity does not include spreading and compacting; thus, no construction activity would take place prior to 7:00 AM.

Truck traffic on a public road is not a construction activity, so the use of trucks on the roadways prior to 7:00 AM does not violate the City or County noise ordinances. Moreover, neither the Centennial nor Brunswick site are within a 500-foot radius of a residential zone in the City of Grass Valley and therefore City of Grass Valley Ordinance 8.28.100 has no relevance to the project. Impacts from noise from use of trucks and dumping on the Centennial site during the proposed hours has been analyzed in Chapter 4.10 of the DEIR.

## Response to Comment Agcy 8-5

The commenter states that the County may also consider splitting the Centennial Site operations off as a separate project and conducting independent environmental review and permitting. Comment noted.

## Response to Comment Agcy 8-6

A Notice of Applicability (NOA) for the water discharge is required by Mitigation Measure 4.8-1(a). As stated in the mitigation measure the owner shall be required to submit quarterly monitoring reports to the Central Valley Regional Water Quality Control Board (CVRWQCB).

General Order R-5-2016-0076 has been replaced with General Order R-5-2022-006 and the relevant sections of Chapter 4.8, Hydrology and Water Quality of the DEIR have been revised for clarification purposes as shown in Response to Comment Agcy 5-11. Upon receipt of the complete Notice of Intent (NOI), if the discharge is deemed eligible for coverage under the General Order, the CVRWQB will issue a Notice of Applicability (NOA). The NOA will specify monitoring and reporting program requirements. All NPDES permits are required to specify requirements for recording and reporting monitoring results. General monitoring provisions of the General Order require that samples taken for the purpose of monitoring be representative of the monitored activity. The monitoring and reporting schedule will be based on the requirements of General Order R-5-2022-006, under the jurisdiction of the CVRWQB. If the CVRWQB believes that more frequent sampling or reporting is required, those requirements will be included in the NOA.

There are currently two other permitted discharges downstream of the project under the same General Order. The Empire Mine State Park discharges to South Fork Wolf Creek and is required to sample for Iron, Manganese, and Arsenic a minimum of once per month. The North Star Water Treatment Facility is required to sample for Iron and Manganese a minimum of once per month and Arsenic a minimum of once per quarter.

https://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/general_orders/r5-2016-0076-01/r5-2016-0076_noas/r5-2016-0076-005_amend.pdf

https://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/general_orders/r5-2016-0076-01/r5-2016-0076_noas/r5-2016-0076-001_noa.pdf

## Response to Comment Agcy 8-7

Underground vehicles will be electric powered only, as stated on page 4.3-50 of the DEIR. The inadvertent reference to “diesel” has been removed from page 3-19 of the DEIR, as follows:

> Mine development in nonmineralized “barren” rock (i.e., non-gold bearing) is expected to result in the production of approximately 500 tons per day (182,500 tons per year) of barren rock. The barren rock would be transported from the tunnel face to the mine shaft (using electric ~~or diesel-~~powered load/haul/dump vehicles, rail cars, and/or conveyors) to underground rock bins located adjacent to the shaft. The rock would then be loaded into the shaft skips, hoisted to the surface, and dropped into one of the compartments of the concrete silo located on the surface. The barren rock will then be transported by trucks on the surface for use as engineered fill.

The above minor change is for clarification purposes and does not affect the adequacy of the analysis contained in the DEIR, nor alter any conclusions.

## Response to Comment Agcy 8-8

As described in Section 3.0 of the DEIR, after full placement of fill at the Centennial and Brunswick Industrial sites to the pad design elevations, hauling of engineered fill (barren rock and sand

tailings) would shift entirely to be utilized in local and regional construction markets. Please also see Master Response 11 – Engineered Fill Utilized in Local and Regional Construction Markets.

## Response to Comment Agcy 8-9

As stated, page 3-40 of the DEIR, back-up power generation would have a capacity to provide approximately 6 MW on a continuous basis and the net load for the operation is approximately 6MW. Therefore, the backup generators have the capacity to power the entire operation if utility power is interrupted. Engineering details, including electrical designs and alarms, would be provided in the submittal of Improvement Plans to Nevada County which require approval before commencement of construction.

## Response to Comment Agcy 8-10

The word "stored" is not used on page 3-26 of the DEIR. Engineered Fill would be placed on approximately 31 acres of the Brunswick Industrial site as described in Chapter 4.7 of the DEIR, within the limits of area and height as shown in Figures 3-7 and 3-8 of the DEIR. These limits define the maximum volume of engineered fill that can be placed on the Brunswick site. Please see Master Response 11 – Engineered Fill Utilized in Local and Regional Construction Markets regarding demand for barren rock or sand tailings. Note that no stockpiles of engineered fill would be kept on the Brunswick site, as all material to be sold in local and regional construction aggregate markets would be kept either underground, or in surface bins at the Brunswick shaft and the storage bay in the process plant.

## Response to Comment Agcy 8-11

Insurance coverage and applicable limits are not environmental impacts that require analysis under CEQA. Explosives transporters would be required to comply with all applicable laws regarding transport of explosives including any statutory or regulatory insurance policy requirements.

## Response to Comment Agcy 8-12

Prior to commencement of initial mine dewatering, the Project Applicant will connect 30 properties in the East Bennett area to the NID potable water system as required in Mitigation Measure 4.8-2(c) of the DEIR.

## Response to Comment Agcy 8-13

The mine rescue team will be comprised of on-site employees of the project.

## Response to Comment Agcy 8-14

This comment does not relate to an environmental impact nor a deficiency with the DEIR. Comment noted.

## Response to Comment Agcy 8-15

The commenter suggest that the various permits shown under the authority of the State Water Resources Control Board Division of Water Rights should be shown as being under the jurisdiction of the Regional Water Quality Control Board (RWQCB). Table 3-11 of the DEIR is hereby revised to show that the specific permits are under the authority of the RWQCB. Comment noted.

| | | |
|---|---|---|
| State Water Resources Control Board ~~Division of Water Rights~~ | 401 (Water Quality) Certification (Clean Water Act, 33 USC 1251: if the project requires Army Corps of Engineers 404 permit) | Discharge into "water of the United States" including wetlands |

| | | |
|---|---|---|
| | General Industrial Activity Stormwater Permit. Notice of Intent (40 CFR Part 122) | Stormwater discharges associated with industrial activity, unless covered by individual NPDES Permit |
| | Spill Prevention Control and Countermeasures Plan (Health and Safety Code 25270 et seq.; 40 CFR Part 122) | Underground storage of petroleum of 42,000+ gallons. Above ground storage with 10,000+ gallons; or any spill affecting surface waters, single tank of 600 gallons, or 1,320 total |

The above minor change is for clarification purposes and does not affect the adequacy of the analysis contained in the DEIR, nor alter any conclusions.

## Response to Comment Agcy 8-16

The commenter requests that the DEIR include maps showing the maximally exposed sensitive receptor related to the health risk assessment. Please see Dudek Memorandum HRA Isopleths – Exhibit D, included in the Final EIR as Appendix K.

## Response to Comment Agcy 8-17

The project design incorporates the extensive use of electric machinery and vehicles and therefore decreases the reliance on fossil fuels to the extent possible. All underground mining and surface processing would be powered by electricity provided by the local utility PG&E. Mitigation Measure 4-3-1(b) requires that where access to alternative-fueled equipment is available, portable diesel engines will be prohibited. As discussed in Section 4.3-4 of the DEIR, the use of fossil fuels has been minimized and use of grid-supplied electricity provides an opportunity for the use of renewably-generated electricity to power project operations. Thus, use of electrically-powered equipment would reduce the project's dependence on fossil-fuel energy supplies and would not be considered an inefficient source of energy demand. The quantity of fuel used, including gasoline and diesel, for operations was considered to generate the emission estimates provided in Appendix E.1 using the emission factors and vehicle assumptions provided in that report. Additionally, a memorandum from Dudek, explaining the expected volumes of gasoline and diesel to be used by the project has been attached to the Final EIR as Appendix M. As further detailed in revisions to the discussion for Impact 4.3-4, the volume of gas, diesel and other energy used by the project is not considered wasteful, inefficient or unnecessary.

**4.3-4 Result in the inefficient or wasteful use of energy. Based on the analysis below, the impact is *less than significant*.**

Implementation of the proposed project would result in the consumption of energy resources during construction, operation, and reclamation activities. The principal forms of energy consumed would be electricity, gasoline, and diesel. The foregoing forms of energy would be consumed by off-road equipment, facilities, stationary generators, and on-road vehicles. Off-road equipment (such as graders, excavators, cranes, et.) and stationary generators would generally be powered by diesel; however, some equipment, such as boring machines, air compressors, locomotives, pumps, and ventilation equipment would be electrically powered. On-road vehicles would demand either diesel or gasoline, with lighter duty vehicles often requiring gasoline while haul trucks and heavier duty vehicles typically require diesel fuel.

In addition to reducing air quality and GHG emissions, APM-AQ-1, Exhaust Emission Controls, would serve to avoid inefficient energy consumption in several ways. First, APM-AQ-1 commits the Project Applicant to using Tier 4 Final equipment throughout project construction, operation, and reclamation. The commitment to the use of Tier 4 engines is further required by Mitigation Measure 4.3-1(b) of this EIR. As a result of the improvements integrated into Tier 4 Final engines (relative to lower tier engines), Tier 4 Final compliant engines are generally the most fuel-efficient models currently available. Consequently, by using Tier 4 compliant engines throughout the construction, operation, and reclamation processes, fuel use by off-road equipment would be minimized, and the off-road equipment used in project implementation would not be inefficient.

As a further means of increasing the efficiency of fuel use associated with project implementation, APM-AQ-1 includes measures to minimize vehicle idling where practical. In general, reducing idling reduces the amount of run-time for engines, which decreases the amount of fuel consumed. Reducing idling time would, therefore, avoid inefficient energy consumption related to off-road vehicle use. Similarly, maintaining equipment in accordance with manufacturer's specifications, as required by APM-AQ-1, ensures that equipment continues to operate efficiently.

Projected fuel use during construction is approximately 161,700 gallons of diesel and 21,488 gallons of gasoline. Projected petroleum use during operation of the project averages to 222,375 gallons per year (165,182 gal/year (diesel) + 57,192 gal/year (gasoline)) over the estimated 11-year period during which engineered fill would be transported by truck to the Centennial and Brunswick Industrial Sites. For the remainder of the life of the project, during which engineered fill is transported longer distances to market, projected annual petroleum use is 403,208 gallons (357,742 gal/year (diesel) + 45,468 gal/year (gasoline)).

In addition to the energy efficiency requirements focused on reducing fuel consumption discussed above, construction and operations would also require operation of electrically powered equipment. Total energy demand during construction is estimated at 16,513 megawatt-hours. Total annual energy demand (PG&E supplied) for the operational lifetime of the project is estimated at 49,613 megawatt-hours. Use of grid-supplied electricity provides an opportunity for the use of renewably generated electricity to power project operations. Unlike fossil-fueled equipment, electric equipment may receive electrical power from sources such as solar, hydro-electric, wind, or biomass, which are sustainable and renewable. The electricity provider for the project area, PG&E, currently utilizes a variety of renewable energy sources to provide electricity to the grid. Thus, use of electrically powered equipment would reduce the project's dependence on fossil-fuel energy supplies and would not be considered an inefficient source of energy demand. Although electricity demand for the project would primarily be met through grid-supplied electricity, in certain instances, such as during power outages or emergency electrical shut-offs, the use of emergency generators would be necessary to provide continued electrical power. Despite the emergency generators being diesel fueled, both of the generators used during project construction and all four of the generators used during project operations, if needed, would be Tier 4 Final engines. As discussed above, Tier 4 Final engines are the most efficient engines currently available, which would ensure that the consumption of fuel by the generators would be minimized to the extent feasible. Moreover, the generators would be used to provide continued operations to critical mining

infrastructure such as pumps, locomotives, and ventilation systems, which are critical to the safety of miners and efficient operation of the mine. Thus, the use of electrically powered equipment would not result in the inefficient or wasteful consumption of energy.

All stages of project implementation would require on-road vehicle use. Light- and heavy-duty vehicles would be used by employees commuting to and from the project sites, as well as for the movement of goods, products, and equipment to and from the project sites. On-road vehicles currently use a variety of fuels including gasoline, diesel, and electricity. California has implemented strict regulations related to fuel efficiency standards for all types of vehicles, and to encourage the proliferation of electrically powered vehicles. Project-related vehicles, including those operated and owned by the Project Applicant, would be required to meet all existing and future state standards, which would ensure that all vehicles operated as part of the project are fuel- and energy-efficient. Finally, by using project-generated fill at the Centennial and Brunswick sites, the project would provide a local source of fill materials to both sites, which would minimize the length of travel for fill material. Providing local sources of fill materials reduces the energy required to transport material, and provides an energy-efficient supply of construction materials.

Based on the above, APM-AQ-1 and Mitigation Measure 4.3-1(b) would ensure that only high-efficiency off-road equipment is used during project construction, operation, and reclamation. Electrically powered equipment used on-site would primarily be served by grid-supplied electricity, which would originate from an increasingly renewably sourced mix of energy, and, if emergency power is required, the emergency generators would be Tier 4 Final compliant engines. On-road vehicles are required to meet stringent state and federal requirements related to fuel efficiency. All project vehicles would be required to comply with the existing requirements, which would ensure that on-road vehicles would be operated in an energy efficient manner. Accordingly, the proposed project would not result in an inefficient, wasteful, and unnecessary consumption of energy, and the impact would be ***less than significant***.

Mitigation Measure(s)
*None required.*

The above revisions to the DEIR provide quantitative estimates of project energy and fuel demand during construction and operations. This information amplifies the current impact discussion of the DEIR, which clearly demonstrates that the project's use of electricity and petroleum would not be wasteful or inefficient due to incorporation of energy- and fuel-efficient technology, including but not limited to, Tier 4 Final Engines in off-road equipment during construction, operation, and reclamation processes. Also, in an effort to reduce fuel consumption, the applicant has committed that all underground equipment will be powered by electricity. The project's annual operational use of electricity in megawatt-hours is only approximately 7% of the amount of electricity used in Nevada County in 2020 (see page 4.3-18 of the DEIR for the Nevada County electricity estimate).

## Response to Comment Agcy 8-18

As stated on page 4.3-89 of the DEIR, The Energy Action Plan (EAP) is not a Qualified GHG Emissions Reduction Plan under CEQA pursuant to the requirements outlined in the CEQA Guidelines, Section 15183.5(D); therefore, no CEQA document can tier from the County EAP. Nevertheless, the compliance of the project with EAP strategies has been analyzed and found to

be consistent with the EAP. Please see Master Response 25 - Nevada County Energy Action Plan.

## Response to Comment Agcy 8-19

The commenter asserts that the discussion in Section 4.3-9 of the DEIR refers only to the project's impacts and does not clearly discuss the cumulative impacts of the project combined with other projects. However, Section 4.3-9 includes the following discussion of cumulative development energy use "Increased efficiency will be ensured in the future as cumulative development occurs due to compliance with the State's robust energy efficiency requirements. For example, the 2019 CBSC has begun phasing in Zero Net Energy requirements by requiring residential projects to meet 100% of their electricity needs through rooftop solar. Cumulative residential development would include rooftop solar to meet 100% of each project's electricity demand. In addition, pursuant to 2019 CBSC, new non-residential buildings associated with cumulative development are also required to be solar ready." (DEIR, p. 4.3-102.) As such, the DEIR's analysis already analyzes the project's cumulative energy use impacts as combined with other cumulative projects. Comment noted.

## Response to Comment Agcy 8-20

Please see Master Response 19 – NSAQMD Criteria Pollution Thresholds during Operations.

## Response to Comment Agcy 8-21

The commenter has not identified a new significant impact that was not addressed in the DEIR; therefore, recirculation is not required. Please also see Response to Comment 8-45 regarding criteria for recirculation.

## Response to Comment Agcy 8-22

The commenter requests that the County submit the project's Final Drainage Report to the City of Grass Valley City Engineer for review and comment. The City of Grass Valley has no direct jurisdiction over the Final Drainage Report. Nonetheless, this comment will be provided to the County's decision makers for their consideration.

## Response to Comment Agcy 8-23

The commenter asserts that the DEIR fails to adequately analyze the fact that the project sites are within the City's sphere of influence and does not analyze specific general plan policies associated with the City. However, the commenter does not identify any specific land use conflicts or impacts, and rather, generally asserts that more analysis is required. Pursuant to General Plan Policy 1.8.4, for all discretionary projects within a City's Sphere of Influence, the County shall first request that the City / Town determine whether or not it desires to annex the project. As required, the City of Grass held a Development Review Committee (DRC) Meeting on September 8, 2020 and determined that the City did not wish to pursue annexation of the project at that time. Furthermore, the City also provided comments to the County from the DRC meeting, which were reviewed as part of the development of the DEIR.

As stated on page 4.9-3 of the DEIR, "While the majority of the Sites are located in the City's sphere of influence and assigned General Plan land use designations by the City, the Sites are located within unincorporated Nevada County and are not proposed to be annexed to the City of Grass Valley." The County evaluated potential land use conflicts in Chapter 4.9 of the DEIR and concluded that potential land use conflicts were less than significant.

## Response to Comment Agcy 8-24

The commenter asserts that mitigation measure 4.10-4 lacks timing and that the Ground Vibration Monitoring Program should be developed prior to operation of the mine. However, Mitigation Measure 4.10-4 is the Ground Vibration Monitoring Program, and is required to be implemented during any blasting on site. Data from the seismographs used during the Ground Vibration Monitoring Program will be used to develop an equation that can be used to modify blasting during subsequent mine operations to minimize impacts. No data can be collected by seismographs until blasting actually occurs at the project and the equation for site-specific ground vibration cannot be developed until measurements of vibrations from blasting are collected. Mitigation Measure 4.10-4 of the DEIR reflects the number and placement of seismographs recommended in the Blasting Report (Appendix M or the DEIR).

Mitigation Measure 4.10-4 is hereby revised as follows to clarify timing of installation and use of seismographs:

> 4.10-4 The Project Applicant shall conduct a project-specific Ground Vibration Monitoring Program, as set forth in this mitigation measure. As part of the Ground Vibration Monitoring Program, the mine shall employ between eight and ten seismographs, which shall be installed prior to any onsite blasting, and used during all blasting of levels above the 1,000-foot level. The seismographs shall be placed at the following locations:
>
> - *One at the Brunswick Shaft;*
> - *One at each of the four corners of the Mine Property;*
> - *One in the Whispering Pines Industrial Park;*
> - *Two at nearby residences; and*
> - *Two travelling seismographs which can change location depending on the weekly/monthly mining plan.*
>
> After the mine has stopped blasting at the proposed shaft and above the 1,000-foot level, only five seismographs would be required for the Ground Vibration Monitoring Program. One seismograph shall be located at the Brunswick Shaft and one in each of the four corners of the mine property. The five seismographs would collect relevant data throughout the entire operation to understand how the ground is transmitting vibration in these areas.
>
> Once mining operations commence, the Project Applicant shall hire a blast consultant to assist with the development of a 95 percent confidence level equation for the site-specific ground vibration. The blast consultant shall assess the data acquired by the seismographs using a linear regression and log-log confidence model to develop an equation that the mine can use to modify blasting, as needed, to ensure vibration levels remain below 0.4 in/s at sensitive receptors.
>
> Results of the Ground Vibration Monitoring Program and the equation for site-specific ground vibration shall be submitted to the Nevada County Planning Department, on a monthly basis, for review.

The above minor changes are for clarification purposes and do not affect the adequacy of the analysis contained in the DEIR, nor alter any conclusions.

## Response to Comment Agcy 8-25

The commenter alleges that the hauling, dumping and compacting activities at the Centennial site will be beyond standard construction hours and will violate noise standards, creating significant noise impacts. However, the DEIR already acknowledges and analyzes the loading and dumping of trucks and spreading and compacting of material during the relevant hours, and concluded that noise impacts would be less than significant. As discussed in Response to Comment Agcy 8-4 above, and contrary to the commenter's assertion, hauling and dumping of loads will occur on the Centennial site between 6:00 AM and 10:00 PM, but no construction activities such as compaction or grading will occur prior to 7:00 AM. The EIR analyzed the noise during the proposed hours and locations of the various activities of the project including trucking, and did not identify any significant noise impacts. The project would comply with the applicable nighttime noise standards during the nighttime (6:00 AM – 7:00AM) hour of activity (See Chapter 4.10 of the DEIR).

Moreover, truck traffic on a public road is not a construction activity, so the movement of truck on the public streets is not a construction activity regulated by noise ordinances as construction noise. Neither the Centennial or Brunswick site is within a 500-foot radius of a residential zone in the City of Grass Valley, so the noise ordinance requirements cited by commenter are inapplicable. Impacts from noise of from trucks and dumping during the proposed hours has been analyzed in Chapter 4.10 of the DEIR.

## Response to Comment Agcy 8-26

As stated on page 4.10-32 the noise increase from the placement and compaction of engineered fill at the Centennial site would be less than significant, based on application of relevant noise standards compared to expected project noise. The DEIR's characterization of the project noise at the Centennial site as "temporary" did not affect the impact analysis, so the commenter's dislike of that characterization is not relevant to the analysis. The commenter also alleges that construction noise will occur "when other construction activities are not allowed"; however, the placement and compaction of engineered fill is scheduled from 7:00AM to 3:30PM on Monday through Friday as stated in the project description and in Table 3-7 of the EIR. The only activities allowed prior to 7:00AM are hauling and dumping of engineered fill.

## Response to Comment Agcy 8-27

In Table 4.10-6 of the DEIR the Baseline Ambient Conditions – Nighttime columns are mislabelled with Lmax shown in the first column and Leq in the second column. The label should be Leq in the first column and Lmax in the second columns (similar to the format of the rest of the table). The second column shows higher decibel values and is clearly representing Lmax. Table 4.10-6 is hereby corrected in the FEIR, on the following page, and this minor labelling error does not affect the analysis presented in the DEIR.

## Response to Comment Agcy 8-28

The intersection of Idaho Maryland Road and Sutton Way currently is an all way stop and this is properly reflected in the Traffic Impact Analysis (TIA) in Appendix O of the DEIR and in Chapter 4.12 of the DEIR.

## Response to Comment Agcy 8-29

The TIA and DEIR incorrectly used the Home-Based VTM per Worker, presented in Table A-3 of the SB743 Report as the threshold of significance for the project. The Total VMT per Service Population presented in Table A-4 should have been used as the threshold of significance in accordance with the Nevada County TIAG. The use of Total VMT per Service Population for Unincorporated Western Nevada County of 18.1 is the most conservative approach and the threshold of significance is 14.3% below the subarea mean with a value of 15.5 VMT per Service

Population. Sections 4.12.2 and 4.12.4 of the DEIR have been updated to reflect these changes in the FEIR, as follows.

Page 4.12-17 of the DEIR is hereby revised as follows:

> **Existing Vehicle Miles Traveled**
> VMT is a metric that accounts for the number of vehicle trips generated and the length or distance of those trips. The available measures of VMT for Nevada County include the following:
>
> - Total VMT – the sum of VMT for all vehicle trips and trip purposes.

**Table 4.10-1**
**Baseline Ambient Conditions and Adjusted Nevada County Noise Standards by Receptor**

| | Baseline Ambient Conditions[1] | | | | | | Applicable Standards After Adjustment | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Daytime[3] | | Evening[3] | | Nighttime[3] | | Daytime | | Evening | | Nighttime | |

Notes:
1. Baseline ambient conditions at each representative receptor were established through extrapolating the Table 4.10-1 data closest to each receptor using a 4.5 dB per doubling of distance decay rate.
2. Receptor locations are indicated on Figure 4.10-2.
3. Daytime = 7:00 AM – 7:00 PM; Evening = 7:00 PM – 10:00 PM; Nighttime = 10:00 PM – 7:00 AM

***Source: Bollard Acoustical Consultants, Inc. (2021).***

- Residential VMT per capita – the sum of VMT for trips originating from home, divided by the number of residents.
- VMT per worker – the sum of VMT for trips from home to work, divided by the number of workers.

In July 2020, Fehr & Peers prepared Senate Bill 743, Vehicle Miles Traveled Implementation for the Nevada County Transportation Commission (NCTC). The NCTC in turn distributed the document to the various agencies within the County so each agency could develop their own significance threshold guidelines. Fehr & Peers recommends that VMT be expressed as a generation rate rather than a ratio. The County's recommended threshold of significance is on a per service population basis (Nevada County Traffic Impact Guidelines, June 2020). Because the proposed project is an industrial land use project, the calculated VMT per employee (worker) is also the VMT per service population~~County determined that the preferred significance threshold metric shall be VMT per worker (i.e., project employee)~~.

The subareas, based on similar travel characteristics and proximity, are recommended to be the following: the City of Grass Valley; the City of Nevada City; the Town of Truckee; Alta Sierra; Lake of the Pines; Lake Wildwood and Penn Valley; the remainder of western Nevada County; and the remainder of eastern Nevada County. Use of a subarea threshold acknowledges the differences in VMT generation in different parts of Nevada County.

Table 4.12-4 presents the results of the VMT measurement analysis that considers trips from outside the model as well as within the NCTC Travel Demand Model (TDM) ~~from several data sources including the NCTC Travel Demand Model (TDM), the California State Travel Demand Model, and MXD+, a trip generation tool developed by Fehr & Peers.~~ As noted in further detail in the Method of Analysis section below, the data in Table 4.12-4 was used to determine the significance threshold for the proposed project. Half of the project is located in the Grass Valley Subarea while half is located in unincorporated Western Nevada County~~The Grass Valley subarea was used as the basis due to the project's proximity to the City~~.

**Table 4.12-4**
**~~Home-Based VMT per Worker~~Total VMT per Service Population**

| Location (SubArea) | NCTC TDM |
|---|---|
| Grass Valley | ~~18.6~~28.0 |
| Nevada City | ~~26.6~~36.2 |
| Truckee | N/A |
| Alta Sierra | ~~27.8~~17.1 |
| Lake Wildwood | ~~34.3~~22.5 |
| Penn Valley | ~~18.6~~18.8 |
| Lake of the Pines | ~~25.0~~16.4 |
| Unincorporated Western Nevada County | ~~N/A~~18.1 |
| Western Nevada County Total | 22.2 |

***Source: KDAnderson & Associates, Inc., 2021.***

In addition, page 4.12-28, Section 4.12.4, Impacts and Mitigation Measures, is hereby revised as follows:

**Vehicle Miles Traveled Standard of Significance**
For the proposed project, a VMT impact may be considered less than significant if:

- The project's total weekday VMT per service population is equal to or less than 14.3 percent below the subarea mean under baseline conditions, or the project reduces the total VMT per service population for the subarea; and
- The project is consistent with the General Plan and the Nevada County Regional Transportation Plan.

As stated above, because the proposed project is an industrial land use project, the ~~County determined that the preferred significance threshold metric shall be~~ VMT per worker (i.e., project employee) is also the VMT per Service Population. The data in Table 4.12-4 was used to determine the significance threshold for the proposed project. Half of the project is located in the Grass Valley Subarea while half is located in unincorporated Western Nevada County. The subarea mean VMT per service population rates are 28.0 for Grass Valley and 18.1 for unincorporated Western Nevada County. The most conservative approach is to use the unincorporated Western Nevada County~~Grass Valley~~ subarea ~~was used as the basis due to the project's proximity to the City~~. Therefore, the proposed project would be considered to result in a significant impact related to VMT if the project would result in a VMT per worker ratio that is less than 14.3 percent below the subarea mean for the ~~Grass Valley~~unincorporated Western Nevada County subarea of 18.~~6~~1.

In addition, Impact 4.12-5, related to VMT, is hereby revised as follows:

**4.12-5 Conflict or be inconsistent with CEQA Guidelines section 15064.3, subdivision (b). Based on the analysis below, the impact is *less than significant*.**

Because the proposed project is an industrial land use project, the ~~County determined that the preferred significance threshold metric shall be~~ VMT per worker (i.e., project employee) is the VMT per service population. The ~~Grass Valley~~unincorporated Western Nevada County subarea was used as the basis ~~due to the project's proximity to the City~~as a conservative approach. As shown in Table 4.12-4, the ~~Grass Valley~~unincorporated Western Nevada County subarea has an associated ~~home-based~~ VMT per ~~worker~~ service population of 18.~~6~~1. As shown in Table 4.12-16~~ on a per worker basis~~, the proposed project is modeled to generate a daily rate per service population (employee) of ~~13.9~~14.4 VMT (~~under 2035 Plus Project Conditions~~in the 2020 base year), which is more than 14.3 percent below the ~~Grass Valley~~unincorporated area metric of 18.~~6~~1 VMT per worker. Therefore, the proposed project would result in a reduced VMT per service population for the applicable subarea.

**Table 4.12-16**
**Rise Grass Valley Project Generated VMT Summary**

| Metric | ~~2035 Future Year~~2020 Base Year |
|---|---|
| ~~Total Daily Project VMT~~ | ~~1,538~~ |
| ~~Maximum Employees on Site (including Centennial employees)~~ | ~~111~~ |
| Daily VMT per ~~Employee~~ Service Population | ~~13.9~~14.4 |
| ***Source: ~~Fehr & Peers~~KD Anderson, 2020~~2~~.*** | |

In addition, because the proposed project is anticipated to employ approximately 312 direct employees during full operations, pursuant to Section L-II 4.1.9 of the Nevada County LUDC, the Project Applicant would be required to submit a detailed analysis of transportation alternatives, documenting feasible measures for reducing auto dependence.

Although the overall project site is not currently served by transit and the Nevada County Transit Services Division does not have plans to bring service to the project area, the nearest bus route to either the Brunswick Industrial Site or Centennial Industrial Site is Route #3, which operates between the Tinloy Street/Bank Street Transit Center and the Nevada County Airport and passes directly by the Centennial Industrial Site. The proposed project would incorporate an area for bicycle racks at the Brunswick Industrial Site, which would provide a minimum of 11 racks (44 bicycle spaces). Pursuant to Nevada County LUDC, additional potential transportation reduction alternatives for the proposed project were identified in the Traffic Impact Analysis prepared for the proposed project, based on the Transportation Demand Management strategies included in the Vehicle Miles Traveled Implementation report prepared by Fehr & Peers for the NCTC, and include the following:

- **Commute Trip Reduction, #3.4.11, TRT-11: Provide Employer-Sponsored Vanpool/Shuttle:** This strategy would make a company sponsored vanpool/shuttle available to allow employees to commute in a single vehicle. Because employees of the proposed project are likely to be coming from throughout the area, the use of specific locations for pick up, such as existing Park-and-Ride lots in the County, would facilitate the reduction of commute vehicles.

  The proposed project could also institute a shuttle service between the project site(s) and the Tinloy Street/Bank Street Transit Center to provide a convenient location for employees to transfer from public transit or to be dropped off. A shuttle could operate several times each day, during the 7:00 AM and 7:00 PM shift changes and at the end of the administrative workday, after 3:30 PM.
- **Commute Trip Reduction, #3.4.3, TRT-3: Provide Ride-Sharing Programs:** This strategy involves the employer providing ride-share coordination and parking facilities to provide information for employees to ride share to and from work. This strategy is intended to match employees by location resulting in a reduction of commute vehicles. Rideshare activities would provide incentives for employees commuting to and from the site. Ridesharing could be coordinated between employees along a similar route from their residence to the work site. The use of existing Park-and-Ride lots may provide a location for employees to meet and commute together, reducing the number of vehicles in the roadway network. Three Caltrans Park-and-Ride locations exist in Nevada County, two in Penn Valley and one in Grass Valley; all are located along SR 20. A Park-and-Ride location also exists in Auburn for employees commuting along SR 49 from Placer County. Incentives may include the use of high-occupancy vehicle (HOV) lanes, less maintenance on a single vehicle due to reduced use, and cost sharing between employees/employer.

  Given that the proposed project would result in a VMT per ~~worker~~ service population ratio that is greater than 14.3 percent below the subarea mean for the ~~Grass Valley~~unincorporated Western Nevada County subarea of 18.~~6~~1, impacts associated with a conflict or being inconsistent with CEQA Guidelines section 15064.3, subdivision (b), would be ***less than significant***.

  Mitigation Measure(s)
  *None required.*

The above-noted errors, which are hereby corrected, did not affect the DEIR's conclusion related to the project's VMT impact, which remains less than significant, as stated in the DEIR. Further details are provided in Response to Comments Agcy 8-38 below.

## Response to Comment Agcy 8-30

The commenter asserts that passenger-car-equivalent (PCE) factors were not used in the traffic analysis to account for the different traffic impact caused by larger trucks; however, the traffic model software used by the traffic consultant account for PCE in the software, and the use of PCE factors are not necessary. As stated on page 25 of the TIA, Synchro and Synco/Simtraffic were utilized for the analysis depending on the intersection characteristics. These programs account for "PCE" to compute levels of service and queues based on the input truck percentages. An explanation has been added to the revised TIA. The Synchro files were updated to reflect the correct truck traffic percentages along the study roadways. All LOS and queuing results and accompanying tables in the TIA were updated to reflect the updated truck percentages. Please see Appendix N to this Final EIR for the updated TIA. No new impacts or mitigations were identified.

## Response to Comment Agcy 8-31

As demonstrated in Response to Comment Agcy 8-30, the commenter has not identified a new significant impact or significant impact that is substantially more severe than disclosed the DEIR; therefore, recirculation is not required. Please also see Response to Comment 8-45 regarding criteria for recirculation.

## Response to Comment Agcy 8-32

Existing and approved projects identified are listed on page 4.12-35 and continues on page 4.12-48 of the DEIR (after a number of figures), and includes the Loma Rica Ranch and Dorsey Marketplace projects. These projects were included and taken into consideration in the TIA and DEIR.

## Response to Comment Agcy 8-33

As discussed on page 4.12-48 of the DEIR, the analysis of the long range 2035 cumulative condition is intended to consider the impact of the proposed project within the context of the Nevada County region buildout projected to occur by 2035. Year 2035 traffic forecasts were based on the most recent NCTC regional travel demand model and includes those projects identified in the EPAP scenario and other reasonably foreseeable cumulative growth.

A connecting road between Idaho-Maryland Road and E. Bennett Road does not currently exist. A road connection between Centennial Drive and E. Bennett St. (WU11) is included in the Nevada County Regional Transportation Plan (NCRTP) as an unconstrained (unfunded) project with no estimated construction date. Without the realization of additional revenues or funding by a future development it cannot be reasonably expected to be constructed prior to the year 2035, and is therefore not within the timeframe analyzed for project-related traffic impacts (See pages 78 and 83 of the NCRTP).

## Response to Comment Agcy 8-34

Table 11 of the TIA provides the projected truck traffic for the site. A Passenger Car Equivalence (PCE) is not necessary to illustrate the truck volumes**.** As stated on page 25 of the TIA, Synchro and Synco/Simtraffic were utilized for the analysis depending on the intersection characteristics. These programs account for "PCE" to compute levels of service and queues based on the input truck percentages.

## Response to Comment Agcy 8-35

The Synchro files were updated to reflect truck traffic percentages along the study roadways. Synchro and Simtraffic account for "PCE" to compute levels of service and queues based on the input truck percentages. The TIA report and its appendices have been revised to reflect this correction; please see Appendix N to this Final EIR.

## Response to Comment Agcy 8-36

All LOS results and accompanying tables in the TIA were updated to reflect the updated truck percentages (Please see Appendix N to this Final EIR). In addition, Tables 4.12-2, 4.12-10, 4.12-11, 4.12-18, and 4.12-19 are hereby revised and provided in strike-through and underline format at the end of this letter. Trucks are fully represented as Synchro and Simtraffic account compute levels of service based on the input truck percentages. No new impacts or mitigations were identified.

## Response to Comment Agcy 8-37

All queuing results and accompanying tables in the TIA were updated to reflect the updated truck percentages (Please see Appendix N to this Final EIR). In addition, Tables 4.12-14, 4.12-15, 4.12-22, and 4.12-23 are hereby revised and provided in strike-through and underline format at the end of this letter. Trucks are fully represented as Synchro and Simtraffic account compute queues based on the input truck percentages. No new impacts or mitigations were identified.

## Response to Comment Agcy 8-38

Please see Response to Comment 8-29. Sections 4.12.2 and 4.12.4 of the DEIR have been updated to use the interpolated 2020 base year conditions in accordance with Section 7 of Nevada County Traffic Impact Analysis Guidelines (June 2020) (TIAG), which results in a project VMT per service population of 14.4.

Service Population is defined in the Nevada County TIAG (page 3) as the total number of residents, employees, and students. The project does not have residents or students and therefore the VMT per Employee is the VMT per Service Population for the project.

Section 7.0 of the Nevada County TIAG states that a project's VMT impact may be considered less than significant if the project total weekday VMT per service population is equal to or less than 14.3% below the subarea mean under baseline conditions.

The Nevada County Transportation Commission Senate Bill 743 Final Vehicle Miles Traveled Implementation report (SB743 Report) dated July 6th 2020 was used as the basis for the adoption of the Nevada County TIAG. Section 4.1 of this report states: *"Recommendation: Use total weekday VMT per service population (residents plus employees and students) as the measure of VMT."* And *"VMT per service population is how much VMT is generated by the residents, employee, and students of the project."*

The use of home-based VMT per resident and home-based work VTM per employee is discussed in Section 4.1 but only for screening purposes stating: Variation among model travel analysis zones (TAZs) in the mix of residential and work-related land uses may create anomalous patterns when screening using total VMT per service population, so, for screening purposes, two other measures may be useful.

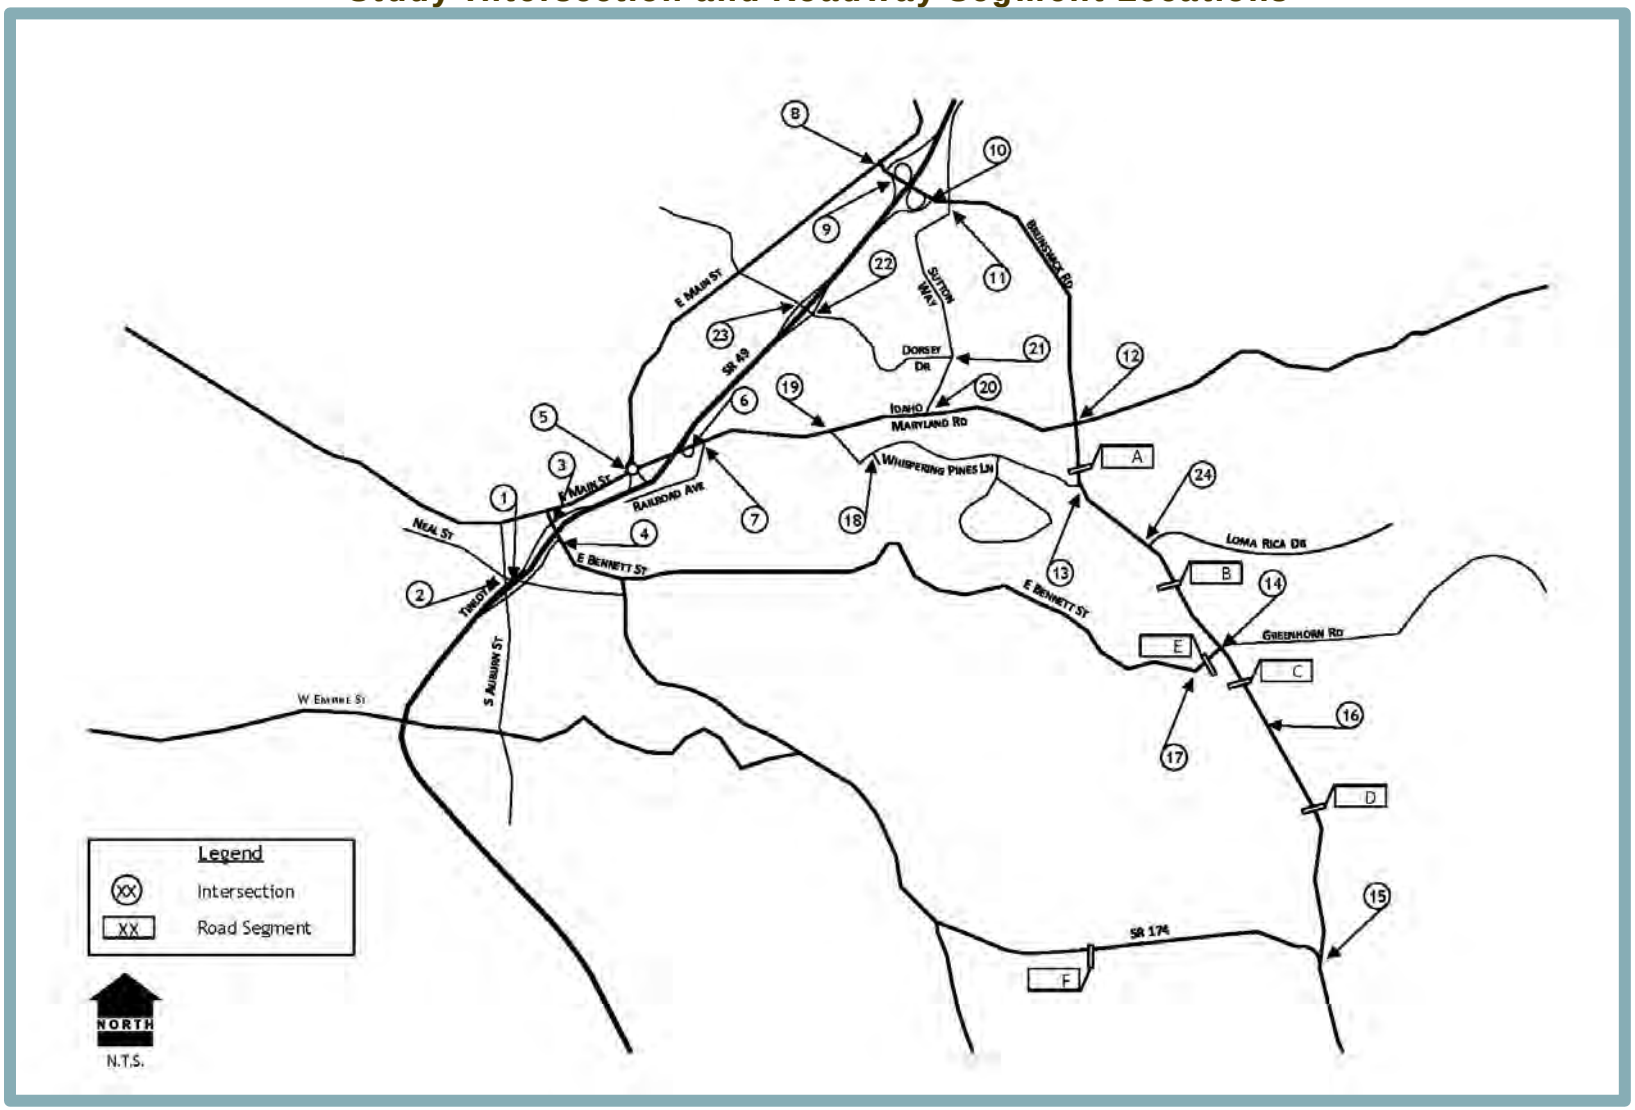
The DEIR incorrectly used the Home-Based VTM per Worker, presented in Table A-3 of the SB743 Report as the threshold of significance for the project. The Total VMT per Service Population presented in Table A-4 should have been used as the threshold of significance in accordance with the Nevada County TIAG. The northern portion of the Brunswick site is partially in the Grass Valley sub-area and the southern portion is in the Unincorporated Western Nevada County subarea. The use of Total VMT per Service Population for Unincorporated Western Nevada County of 18.1 is the most conservative approach and the threshold of significance is 14.3% below the subarea mean with a value of 15.5 VMT per Service Population. Sections 4.12.2 and 4.12.4 of the DEIR have been updated to reflect these changes, as shown in Response to Comment Agcy 8-29. The above-noted errors, which are corrected in this Final EIR, did not affect the DEIR's conclusion related to the project's VMT impact, which remains less than significant, as stated in the DEIR.

## Response to Comment Agcy 8-39

Figure 4.12-1 of the DEIR has been updated (see following page), along with Figures 3, 6A and 6B of the TIA (see Appendix N of this Final EIR) to reflect the roundabout at Main Street/Idaho Maryland Road and the southbound off-ramp at Brunswick Road has been added. No changes to the analysis or conclusions of the DEIR result from these minor corrections.

## Response to Comment Agcy 8-40

Figures 4.12-2 through 4.12-4 and Figures 4.12-7 through 4.12-24 of the DEIR are derived from the TIA. The intersections are generally orientated with north towards the top of the page as indicated by the north arrow in each figure. Figure 4.12-1, as shown on the following page, provides an overview map showing the numbered intersections which assists to determine the orientation of the intersection figures. The street names in each intersection figure are not intended to assist with orientation.



## Response to Comment Agcy 8-41

The historic mining operation averaged approximately 1,000 tons per day of production in the years before the forced closure in 1942. The historic operation constructed a new headframe in 1942 with the intention of increasing mining depth to 5000 ft and doubling production to 2,000 tons per day. Therefore, a level of production of 1,000 tons per day is not speculatively large.

The number of years is not relevant in the analysis of Alternative 4. There is a finite amount of economic gold mineralization at the project, the extent of which is not known at this time and will likely not be known until it is depleted. If this given mass of material is mined at ½ of the rate it will take twice as long to complete mining.

The commenter proposes an alternative where the throughput is cut to 500 tons per day and the life of the mine remain the same length of time. Therefore, total mining would be 50% of the material mined in the base case. This alternative has already been examined in the DEIR (Alternative #4) and would not reduce any significant impact to less than significant. The significant and unavoidable aesthetics, construction noise, and traffic intersection impacts would remain significant and unavoidable. This alternative may be inconsistent with several policies of the General Plan (reduced employment, taxes, etc.) as explained on page 6-36 of the DEIR.

**Figure 4.12-1**
**Study Intersection and Roadway Segment Locations**

***Source: KDAnderson & Associates, Inc., 20221.***

## Response to Comment Agcy 8-42

The commenter asserts that the proposed 80-year permit term is extreme and unprecedented in California. However, this is assertion incorrect. Permit terms of 100 years are routinely approved for large mining operations around California. As an example, Madera County approved a 100-year permit for the Vulcan Austin Quarry, which is a surface-mining operation that produces construction aggregate. Long permit terms are commonly requested for large mining operations because they are capital intensive, and it is not economically feasible to invest tens or even hundreds of millions of dollars on a project, when the number of years in which to obtain return on that investment are limited to only a few decades. The commenter presumes that a 500-tons per day throughput combined with a 30-year permit term is sufficient; but provides no evidence that this drastic change in the economics of the project would be feasible financially. Notably, the County already analyzed the 500-tons per day throughput alternative as Alternative 4 in the DEIR. The commenter also does not explain how the shorter permit term would reduce any significant impacts of the project. A shorter permit term would not avoid any of the significant impacts of the project, but would have less economic benefits to the County and would also potentially fail to meet one or more project objectives.

## Response to Comment Agcy 8-43

The construction of a commercially viable, financeable, major underground gold mine operation that will produce 1,000 tons per day of gold mineralization and providing of jobs are project objectives. The complete elimination of the engineered fill placement on both Centennial and the Brunswick sites is not provided as an alternative. Such an alternative would not provide sufficient certainty for the financing of the construction of a major underground gold mine as it does not allow for a minimum amount of guaranteed storage space required to pay back the initial capital to construct the mine. The trucking of all materials off-site would also increase the project emissions due to the longer hauling distance versus the placement of fill on the Brunswick and Centennial sites.

## Response to Comment Agcy 8-44

The DEIR has determined that the project will have a significant and unavoidable impact to aesthetics. Page 6-3 of the DEIR refers to the less-than-significant impact that would occur related to substantial adverse effects on scenic vistas.

## Response to Comment Agcy 8-45

Please see Responses to Comments Agcy 8-2 through Agcy 8-44. The commenter has not identified a new significant impact that was not addressed in the DEIR or any other deficiency requiring recirculation; therefore, recirculation is not required. Section 1.4 of the Introduction chapter of this Final EIR includes a detailed discussion of the criteria for recirculation set forth in CEQA Guidelines Section 15088.5, demonstrating that recirculation is not required. The majority of that discussion is repeated here for convenience.

Pursuant to CEQA Guidelines Section 15088.5, Recirculation of an EIR Prior to Certification, a lead agency is required to recirculate an EIR when significant new information is added to the EIR after public notice is given of the availability of the draft EIR for public review under Section 15087 but before certification. New information added to an EIR is not “significant” unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect (including a feasible project alternative) that the project’s proponents have declined to

implement. Pursuant to 15088.5(a), "Significant new information" requiring recirculation include, for example, a disclosure showing that:

> (1) A new significant environmental impact would result from the project or from a new mitigation measure proposed to be implemented.
> (2) A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance.
> (3) A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.
> (4) The draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded. (*Mountain Lion Coalition v. Fish and Game Com.* (1989) 214 Cal.App.3d 1043)

The following discussion will evaluate the four above criteria and demonstrate that the changes to the DEIR text presented in Chapter 3 of this Final EIR do not require recirculation of the DEIR.

1. A new significant environmental impact would result from the project or from a new mitigation measure proposed to be implemented.

Pursuant to CEQA Guidelines Section 15088.5(b), recirculation is not required where the new information added to the EIR merely clarifies or amplifies or makes insignificant modifications in an adequate EIR. Chapter 3, Revisions to the Draft EIR Text, of this Final EIR includes several minor changes to the DEIR text as a result of public comment that serve the purpose of clarifying or amplifying the discussion in the EIR without identifying new significant impacts. The majority of modifications consist of small, targeted revisions, consisting of minor additions or deletions. A few modifications involve larger additions of text, but the relevant criterion is not the extent of the modification, but rather whether the added text identifies a new significant impact, which is not the case. See Section 1.4 of the Introduction Chapter of this Final EIR for further discussion.

As shown above, in response to public comment, it was determined that the truck traffic percentages along study roadways needed to be updated in the transportation analysis. These corrections were made to the transportation analysis, an updated version of which is included as Appendix N to this Final EIR; and Chapter 4.12, Transportation, of the DEIR has been revised accordingly in this Final EIR. For example, Tables 4.12-2, 4.12-10, 4.12-11, 4.12-18, and 4.12-19 of the DEIR, reporting study intersection levels of service (LOS), and Tables 4.12-14, 4.12-15, 4.12-22, and 4.12-23 reporting study intersection queues, were updated in strike-through and underline format. However, as demonstrated in this Final EIR, in no case do the revisions trigger a new significant impact at study intersections, when comparing the updated values to the thresholds of significance used in the DEIR. Thus, these corrections do not warrant recirculation of the EIR.

As also shown above, the DEIR incorrectly used the Home-Based VTM per Worker, presented in Table A-3 of the SB743 Report,[4] as the threshold of significance for the project. The Total VMT per Service Population presented in Table A-4 should have been used as the threshold of significance in accordance with the Nevada County Traffic Impact Analysis Guidelines (June

[4] The *Nevada County Transportation Commission Senate Bill 743 Final Vehicle Miles Traveled Implementation Report* (SB743 Report), 2020.

2020). The northern portion of the Brunswick Site is partially in the Grass Valley sub-area and the southern portion is in the Unincorporated Western Nevada County subarea. The use of Total VMT per Service Population for Unincorporated Western Nevada County of 18.1 is the most conservative approach and the threshold of significance is 14.3% below the subarea mean with a value of 15.5 VMT per Service Population. As shown in updated Table 4.12-16, the proposed project is modeled to generate a daily rate per service population (employee) of 14.4 VMT, which is more than 14.3 percent below the unincorporated area metric of 18.1 VMT per worker (i.e., 15.5). Sections 4.12.2 and 4.12.4 of the DEIR have been updated to reflect these changes, as shown in Response to Comment Agcy 8-29. The above-noted errors, which are corrected in this Final EIR, did not affect the DEIR's conclusion related to the project's VMT impact, which remains less than significant, as stated in the DEIR.

As discussed above, the remaining revisions to the DEIR, as presented in Chapter 3 of this Final EIR, are small, targeted revisions that serve to clarify or amplify the existing adequate DEIR. Many of these minor modifications pertain to mitigation language – see criterion #3 below. Please also refer to Chapter 3 for a review of those changes.

In summary, recirculation of the EIR is not required pursuant to criterion 1 of 15088.5.

2. A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance.

This criterion pertains to whether the Final EIR provides significant new information showing that a substantial increase in the severity of an environmental impact already identified in the DEIR would occur unless mitigation measures are adopted that reduce the impact to a level of insignificance. Nothing in the responses to comments, nor in the changes to the DEIR text shown in Chapter 3 of this Final EIR, results in a substantial increase in the severity of a significant environmental impact identified in the DEIR. Recirculation of the EIR is not required under this criterion.

3. A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.

As shown in Chapter 3 of this Final EIR, as a result of public comment, several minor modifications are made to mitigation measures included in the DEIR. Under *Laurel Heights Improvement Ass'n v Regents of Univ. of Cal.* (1993) 6 C4th 1112 (*Laurel Heights II*) and 15088.5(a)(3), when information added to the Final EIR consists of a suggested new project alternative or mitigation measure, recirculation is only required if the new alternative or mitigation measure meets all of the following criteria:[5]

- It is feasible;
- It is considerably different from the alternatives or mitigation measures already evaluated in the Draft EIR;

[5] Stephen L. Kostka and Michael H. Zischke. *Practice Under the California Environmental Quality Act, Second Edition, March 2022 Update, Volume 2*. March 2022, pg. 16-21.

- It would clearly lessen the project's significant environmental impacts; and
- It is not adopted.

Recirculation is only required if *each* of the above tests is met.

In all cases where this Final EIR makes modifications to mitigation measures included in the DEIR, the updated mitigation measures are feasible and the applicant has agreed to implement the updated mitigation measures. No new mitigation measures are identified in this Final EIR, only revised mitigation measures that are not considerably different from the mitigation measure language already included in the DEIR. Thus, this criterion is not triggered by the minor modifications to mitigation measures and recirculation of the EIR is not required.

With respect to the portion of the comment pertaining to alternatives, several commenters suggested one or more additional alternatives for the County to consider. As discussed in this Final EIR, Section 6 of the DEIR considered project alternatives. As summarized in DEIR section 6.2, and provided in CEQA Guidelines section 15126.6, an EIR shall provide a reasonable range of alternatives that achieves the project objectives but avoids or reduces significant project impacts. The alternatives analysis is not required to consider every project alternative but is governed by a "rule of reason" that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice." The alternative analysis in the DEIR considered nine different alternatives. Five alternatives were considered but rejected from detailed analysis since they did not meet most project objectives, were infeasible, and/or did not avoid significant project impacts. Four alternatives were analyzed in detail (see DEIR section 6.3.) The County believes this provides a reasoned choice of alternatives for consideration by the public and decisionmakers. This Final EIR demonstrates how the alternatives proposed by the commenters are either not considerably different from others previously analyzed in that they are not anticipated to eliminate any of the significant impacts of the project, and/or they are not feasible. Thus, this criterion is not triggered and recirculation of the EIR is not required.

4. <u>The draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded.</u>

According to Kostka and Zischke, this test for recirculation is based on the type of wholesale omission of information found in *Mountain Lion Coalition v. Fish & Game Comm'n*, in which the Draft EIR omitted any analysis of cumulative impacts, and a detailed analysis was first provided in the final EIR.[6] The record clearly demonstrates that no such wholesale omissions have occurred with the Idaho-Maryland Mine DEIR.

<u>Conclusion</u>

The above discussion (see also Section 1.4 of the Introduction Chapter) demonstrates that none of the 15088.5 criteria for recirculation are met.

21 January 2022

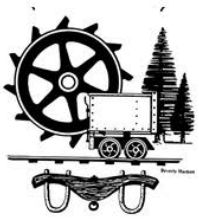
Matt Kelley, Senior Planner
Nevada County Planning Department
950 Maidu Avenue, Suite 170
Nevada City, Cal., 95959

Via email: Idaho.MMEIR@co.nevada.ca.us

Dear Mr. Kelley,

At this morning's meeting, the Nevada County Historical Landmarks Commission approved these comments on the Draft Environmental Impact Report (Draft) for the Idaho-Maryland Mine Project.

**Agcy 9-1**



We express no views on the many environmental, health and safety issues presented by this ambitious project. With respect to the historical preservation issues, we note the following:

**Agcy 9-2**

1. Evaluation of the proposed project must start with the fact that in 1984, the Board of Supervisors declared the Idaho-Maryland Mine Site a Historical Landmark--NEV 33. This project should be evaluated in that context and not whether the Mine Site is on the national or state historical registers.

**Agcy 9-3**

2. The Draft assumes that the County's designation was limited to the area the Draft calls the Centennial Site, which is reportedly outside the project area, and concludes that therefore the Board's determination that it is a historical landmark "need not be addressed." That is at best incorrect; at worst disingenuous. The designation was for the entire Idaho-Maryland Mine, "one of the 'Big Three';" not merely the portion of the mine around the Centennial and Whispering Pine Roads, where its headquarters building is located. The Newsome drill, specifically mentioned in the designation, was extensively used outside the Centennial Site, The fact that the Mine Site is a historical landmark must be addressed.

**Agcy 9-4** 3. The Commission does not have engineering expertise to enable it to judge whether the work the developer is proposing will adversely impact the historical features of the Mine. We expect the County to do that.

**Agcy 9-5** 4. We had earlier noted a concern that the Round Hill shaft be preserved. It does not appear that that will happen.

**Agcy 9-6** 5. We remain of the view that sharing records will not mitigate any harm the project might cause.

**Agcy 9-7** Finally, the Draft acknowledges the significant impact that Errol MacBoyle had on Nevada County. If this project is permitted to proceed, we suggest that the developer be required to erect a suitable monument commemorating Mr. MacBoyle. Currently, there is none such in the County.

**Agcy 9-8** We look forward to reviewing a draft Environmental Impact Report which properly and adequately considers the historical features of the landmark that is the Idaho-Maryland Mine Site.

Yours truly,

Bernard Zimmerman

Bernard Zimmerman, Chair

cc. Landmarks Commissioners
Gage McKinney

## AGENCY LETTER 9: BERNARD ZIMMERMAN, NEVADA COUNTY HISTORICAL LANDMARKS COMMISSION

### Response to Comment Agcy 9-1

The commenter states that the Nevada County Historical Landmarks Commission (Commission) approved the following comments at its January 21, 2022 meeting and expresses no views on the environmental or health and safety impacts of the project. Comment noted. This is an introductory comment and does not provide a comment on any environmental issue associated with the project.

### Response to Comment Agcy 9-2

The commenter states that "evaluation of the project must start with the fact that in 1984, the Board of Supervisors declared the Idaho-Maryland Mine [IMM] Site a Historical Landmark." The County's environmental review is required to comply with the requirements of the California Environmental Quality Act (CEQA). As it pertains to cultural resources, CEQA Appendix G outlines four criteria the environmental document should evaluate. Two of the four pertain to significant changes to a historical or archaeological resource as defined by Public Resources Code section 15064.5. DEIR Chapter 4.5 includes analysis of identified historic and archaeological resources consistent with CEQA Appendix G, which was supported by a site-specific cultural resources survey prepared by a qualified archeologist meeting the Secretary of the Interior's Professional Qualification Standards. (DEIR, Appx. G.) The DEIR found that any substantial adverse changes to historical or archaeological resources would be less than significant after mitigation. (DEIR, pp. 4.5-22, 30.)

### Response to Comment Agcy 9-3

The commenter states that the DEIR inaccurately assumes County's designation of the IMM as a Nevada County Historical Landmark (NEV-33) falls outside the Area of Potential Effects. It is unclear what records the commenter is referencing to make an assertion that NEV-33 included the entire IMM. The Project Applicant's cultural resources expert and the County conducted coordination with Bernard Zimmerman, chair of the Nevada County Historical Landmarks Commission. As outlined in the DEIR, significant outreach and research was undertaken to assess the NEV-33 landmark. (DEIR, p. 4.5-19–21.) Based on this research, the County concluded NEV-33 is outside the project boundary. If, as asserted by the commenter, NEV-33 includes the entire IMM, then this feature was analyzed in the cultural resources technical study and DEIR. Impact 4.5-1 looked at the remaining aboveground and underground components of IMM and concluded the remaining above-ground facilities did not meet NRHP or CRHR criteria. The underground components of Idaho Maryland Mine, despite being inaccessible, could be a contributing element to the Idaho Maryland historic district and a potentially significant impact could occur. Mitigation Measure 4.5-1(a) was provided that reduces this impact to a less than significant level. (DEIR, p. 4.5-22.)

### Response to Comment Agcy 9-4

The commenter states it does not have engineering expertise to determine whether the project will impact the historical features of the IMM. Comment noted. Please see Responses to Comments Agcy 9-2 and Agcy 9-3.

### Response to Comment Agcy 9-5

The commenter states it is concerned that the Round Hill shaft will not be preserved. The Round Hill shaft will not be used as part of the project and is not within the limits of proposed surface disturbance.

## Response to Comment Agcy 9-6

The commenter states that it believes sharing records will not mitigate any harm the project might cause. Comment noted. Please see Master Response 1.

## Response to Comment Agcy 9-7

The commenter suggests that should the project be approved, the Project Applicant should be required to erect a monument in dedication of Errol McBoyle. Comment noted. Please see Master Response 1.

## Response to Comment Agcy 9-8

The commenter states that it looks forward to reviewing a DEIR that adequately considers the historical features of the IMM. This is a conclusory comment and does not provide a comment on an environmental issue associated with the project. Please see the above responses.

**Agency Letter 10**

# Nevada Irrigation District

Water for Life

VIA EMAIL: Idaho.MMEIR@co.nevada.ca.us

March 25, 2022

Mr. Matt Kelly, Senior Planner
Nevada County Planning Department
950 Maidu Avenue, Suite 170
Nevada City, CA 95959-7902

**Re: Nevada Irrigation District Comments for the Idaho Maryland Mine Project Draft Environmental Impact Report**

Dear Mr. Kelly:

Nevada Irrigation District (NID) is in receipt of the Draft Environmental Impact Report (DEIR) for the Idaho Maryland Mine Project. This letter conveys recommendations and concerns regarding the project that are germane to NID's statutory responsibilities. The comments are categorized by type.

**East Bennet Road Potable Waterline**

**Agcy 10-1**

The DEIR proposes the installation of a NID potable water line along East Bennett Road to provide an alternate source of water should existing ground water wells be depleted from mine dewatering. The DEIR depicts the pipeline as being contained with the existing right-of-way along East Bennet Road; however, NID will require the pipeline to interconnect with NID's existing water distribution system in the Whispering Pines Lane area. The connection to existing NID infrastructure will necessitate the crossing of multiple parcels that do not contain an existing roadway/right-of- way. Additionally, connection to NID will occur near Clydesdale Court, which will require a short section of alignment within the right-of-way along Whispering Pines Lane. The Draft EIR does not contemplate this cross-country extension nor the short run up Whispering Pines Lane. NID expects the complete alignment of the East Bennett potable water line including the interconnection

1036 West Main Street, Grass Valley, CA 95945 • (530) 273-6185 • nidwater.com

on Whispering Pines Lane be included in the final EIR and be identified in the conditions of approval for the project. In addition, all easements necessary for construction and ongoing maintenance of the new pipeline shall be acquired by the Applicant and conveyed to NID prior to acceptance of the new potable line. All costs for the above must be borne by the Applicant.

**Agcy 10-2**

The DEIR makes multiple references to the construction of the East Bennet potable water line being constructed to County guidelines. However, NID is the responsible agency for potable water infrastructure; therefore, all construction involving, or connecting to NID infrastructure must be constructed to NID standards. This correction as it relates to potable water infrastructure is necessary throughout the document.

**East Bennet Road NID Potable Water Connection Mitigations**

**Agcy 10-3**

The DEIR requires connection of 30 properties along East Bennett Road (4.8-29(c)) that are currently supplied water via wells. Properties that connect to NID's potable water line and keep their existing wells will require a Double Check Valve (DCV) to prevent any potential backflow into NID's system. DCV installation will increase initial installation costs and require a monthly fee on the consumptive water bill. NID considers the additional installation and ongoing DCV costs as a necessary part of mitigation and should be paid for by the Applicant for the duration of dewatering and mine operations.

**Agcy 10-4**

The Applicant proposed to cover the connection and consumptive costs of NID potable water usage for parcels along East Bennet Road. The mitigation includes paying for all connection costs as well as covering the consumptive rate for up to 400 gallons per day. 400 GPD does not match the amount of water proposed within the Final Idaho Maryland Mine Water Supply Assessment provided to NID. The Water Supply Assessment estimates the average consumption of the 31 parcels to be .4 gallons per minute per dwelling. This equates to a total daily usage of 576 gallons per day and should be the amount of consumptive use the Applicant will pay as a mitigation for any connection along the East Bennett corridor. During the WSA hearing, NID's Board of Directors expressed serious concerns that the number of impacted wells could far exceed the 30 estimated by the DEIR. NID proposes the Applicant conduct a more extensive and robust well and ground water monitoring effort prior to and during any dewatering.

**Agcy 10-5**

Should the number of private wells impacted exceed the 30 that the Applicant estimates, NID believes the Applicant should guarantee and include in its proposed mitigation potable water for each well that is impacted.

**Agcy 10-6**

The DEIR includes a mitigation measure to pay for consumptive water use for parcels along East Bennet Road that connect to NID until the property is sold by the owner, or until the property is annexed into the City of Grass Valley. NID believes the Applicant

should cover cost of consumptive use for each impacted well in the volume stated above (regardless of ownership or annexation) for as long as the project is operating and for a period of 24 months after project is complete or abandoned. This includes initial mine dewatering as well as continued mine operations

**Agcy 10-7** In order to establish a baseline of the number and quality of wells outside of the East Bennett area, NID suggests the Applicant undertake advance sampling of both water quality and production for the wells located in the Woodrose, Greenhorn and Beaver Lane areas.

**Agcy 10-8** The estimates within the GHG emissions modeling (page 351) assumes 26 residences would be switched from well water to NID potable water. Other portions of the DEIR require connection of 30 parcels to NID's potable water system. This discrepancy should be corrected, and the total amount of water use should match the WSA document of .4 gallons per minute per dwelling unit.

**Area of Ground Water Depletion**

During the WSA hearing, NID's Board of Directors expressed serious concerns that the number of impacted wells could far exceed the 30 estimated by the DEIR. NID proposes the Applicant conduct a more extensive and robust well and ground water monitoring effort prior to, and during any dewatering. Should the number of private wells impacted exceed the 30 estimated by the Applicant, NID believes the Applicant should guarantee and include in its proposed mitigation potable water for each well that is impacted.

**Agcy 10-9** The DEIR includes modeling analysis of anticipated effects to ground water levels after initial mine dewatering and long-term ground water levels related to general operations over the term of the project. The document specifies that the Applicant will implement a rigorous Ground Water Monitoring Plan (GWMP) to assess how the hydrogeologic system responds to mining. The GWMP is proposed to establish multiple monitoring wells to provide data analysis of groundwater throughout the project area. NID requests the monitoring wells be placed near locations with the greatest concentration of existing ground water wells, specifically the Greenhorn, Woodrose, and Beaver Lane areas. The strategic placement of monitoring wells will provide an early warning of any adverse effects of dewatering. The monitoring wells should mirror the average depth of the residential wells in the area and be in sufficient number and locations to provide for accurate data. Early awareness will allow the Applicant to halt dewatering and develop alternative water supply options for affected areas.

**Agcy 10-10** One of the potential outcomes of dewatering the mine includes the negative effect to local ground water well production beyond the wells that have already been identified to be impacted in the DEIR. As referenced in the DEIR, the Applicant will be required, at their

cost, to provide an alternate water supply for any well impacted. However, there is no financing mechanism to ensure any additional wells that are impacted beyond the 30 wells identified are able to connect to potable water. NID, as the sole surface water provider in the area, is concerned that the level of infrastructure necessary to extend water to affected wells beyond Bennet Road area would come at a substantial cost. NID estimates extending infrastructure and connecting customers in the Greenhorn, Woodrose, and Beaver area is estimated to be $14 Million. These costs include both pipeline costs and connection fees. Additionally, construction of this magnitude will require a substantial amount of time to complete. NID requests that a mitigation measure and condition of approval require the Applicant to put forth bonds or other form of financial security to cover the costs of such infrastructure for a period of 5 years beyond the completion of initial dewatering of the mine. This will help ensure the communities surrounding mine operations will have some assurance of funding to complete an alternate water supply should it become necessary.

**Wolf Creek Discharge**

The DEIR proposes to dewater the underground workings of the Idaho Maryland Mine, via pumping, treatment, and discharge operations to the South Fork of Wolf Creek. NID is an authorized diverter of imported and natural flows in Wolf Creek. The location of NID's diversion will allow for the recapture of the treated ground water discharge from the Mine. To properly manage flows, promote water efficiency, and protect habitat in Wolf Creek, NID will need access to real-time discharge flows into Wolf Creek. NID recommends a publicly accessible web page that provides real time data along with flow trending over a one-week period. Additionally, any planned outage in the treatment process that would interrupt flows into Wolf Creek should be communicated to NID one week in advance. This information will allow NID to adjust imports into Wolf Creek to meet the needs of end users and maximize beneficial use.

**Agcy 10-11**

As stated above, NID diverts a mixture of natural and imported flows from Wolf Creek to provide irrigation water to 715 customers. While NID does not have jurisdiction over water quality flowing into Wolf Creek, NID, along with Nevada County Environmental Health, need to be notified in the event of a spill or other contaminating event. Early notification allows NID to respond in a manner that will allow isolation of flows to protect our customer base, many of which utilize this water in home for incidental uses.

**Preservation of Historic Storm Water Flow Volume in Wolf Creek**

**Agcy 10-12**

NID exercises the discharge of water from our canal systems during emergency, or storm related events. Many of these natural channels join or cross through the Brunswick site. The ability to continue utilizing these channels to spill water into Wolf Creek shall be preserved and maintained at the levels of historic use. NID has discharge records up to

11 CFS into the head waters of the South Fork of Wolf Creek on the Southeast end of the Brunswick Site. The second spill channel intersects the Brunswick property near Bennet Road on the Northwest edge of the Brunswick site. Flows into Wolf Creek at this location have been recorded up to 35 CFS. NID requests that a mitigation measure be included to ensure the volume of Mine discharge water to Wolf Creek will not limit storm flow capacity during storm events.

**Potable Water Connection to Mine**

Agcy 10-13

Lastly, NID's Rules and Regulations require a reduced pressure backflow prevention device on all commercial or industrial connections to our treated water systems. This will require a retrofit of any existing connections prior operations at both the Brunswick and or Centennial sites. Installation of backflow prevention devices will protect the community drinking water system from an over pressuring event within the mines water system. These devices, and the costs of installing them will need to be paid for by the Applicant.

Again, thank you for providing a copy of the Notice of Preparation for the Idaho Maryland Mine. The District looks forward to working collaboratively with the County and Rise Grass Valley. If you have any questions or would like additional information, please contact me at (530)-271-6882.

Respectfully Submitted,

Armon "Chip" Close
Water Operations Manager

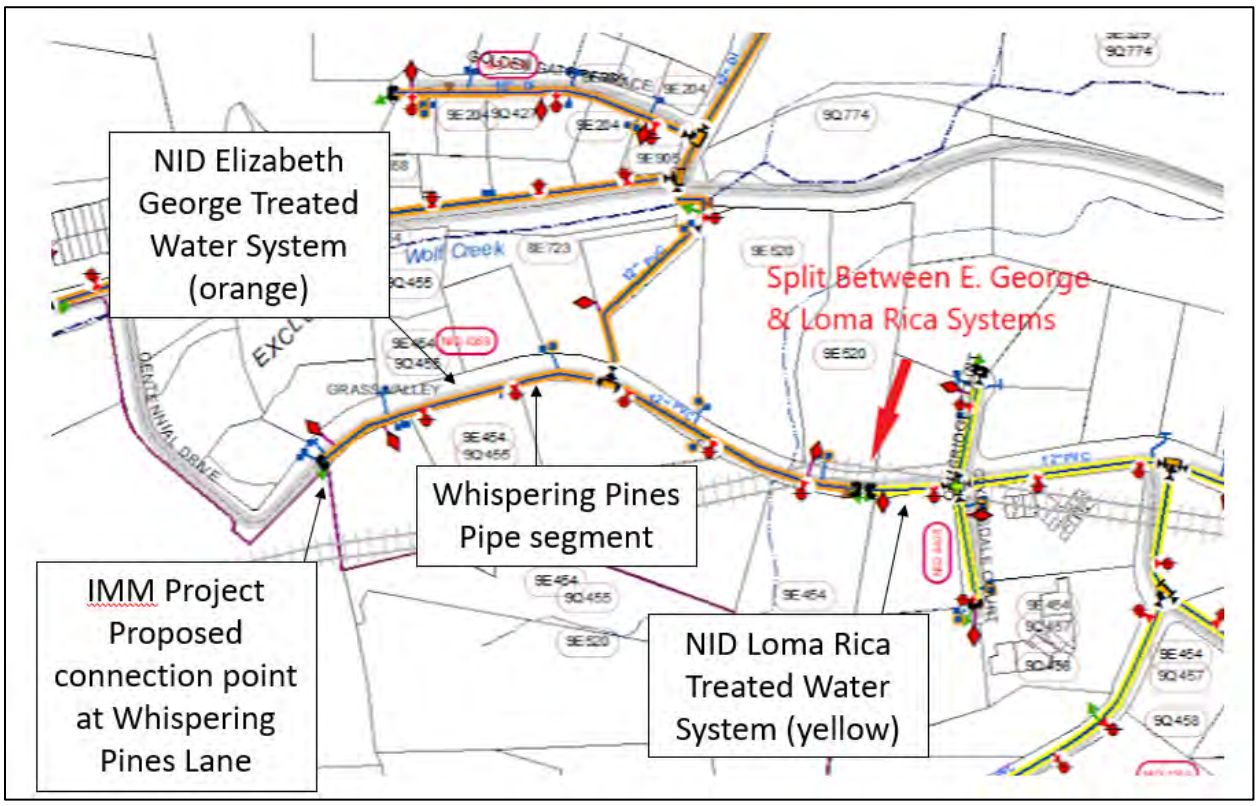
## AGENCY LETTER 10: ARMON CLOSE, NEVADA IRRIGATION DISTRICT

### Response to Comment Agcy 10-1

The Nevada Irrigation District (NID) commented that the proposed potable water line would need to interconnect with the existing NID water line in the Whispering Pines Lane area, requiring additional rights-of-way and easements for installation of infrastructure on parcels where easements/rights-of-way do not presently exist. NID asserts that the DEIR did not contemplate the required interconnections or easements; however, the DEIR does contemplate the need for these interconnections and easements/rights-of-way as discussed below.

The proposed water pipeline design interconnects with NID's existing water distribution system on Whispering Pines Road, as shown in Figures 3-2, 3-9, and 3-15 of the DEIR and described on page 3-36 of the DEIR.

Further, the applicant has submitted an easement agreement with the Use Permit application to allow the construction of the pipeline from E. Bennett Road to the Centennial site and grant easements to NID pursuant to NID standards.



https://www.nevadacountyca.gov/DocumentCenter/View/33587/Rise-Willman-NID-Easement-Agreement---ADDED-392020

The applicant has submitted detailed drawings with the Use Permit application showing the pipeline route and property boundaries.

https://www.nevadacountyca.gov/DocumentCenter/View/33572/Pipeline-Easements-1---ADDED-392020

Additionally, the commenter specifically states that the DEIR does not contemplate the interconnection with NID system on Whispering Pines Lane near Clydesdale Court, which will require a short section of alignment within the right-of-way along Whispering Pines Lane. The commenter suggests that the connection will require the crossing of multiple parcels that do not contain an existing roadway/right-of-way; however, this is not correct. As shown in the figure below (based on map of NID pipeline system provided to applicant by NID) the Elizabeth George Treated Water System and Loma Rica Treated Water Systems have pipelines that are directly adjacent within the roadway and could be connected without obtaining any new right-of-way or easements and without new significant disturbance. This more feasible connection method would transfer customers on Whispering Pines Lane from the Elizabeth George system to the Loma Rica system in order to complete a closed circuit with the proposed water line extension for the project along E. Bennett Road.

Given that there are options to provide the connection discussed by NID without crossing the parcels as suggested, it would be speculative to assume crossing of other parcels is required. Further, while there are multiple technical methods that could be used to connect the water systems such as pressure balancing systems, the specific details regarding interconnection and balancing of pressures and allocation of water from different NID water treatment plant circuits is an engineering level detail and engineering level detail is not required in an EIR. (*Dry Creek Citizens Coalition v. County of Tulare* (1999) 70 Cal.App.4th 20, 26.)

Mitigation Measure 4.8-2(c) of the DEIR is hereby revised to clarify these necessary interconnections and that all easements necessary for construction and ongoing maintenance of the new pipeline shall be acquired by the applicant and conveyed to NID prior to acceptance of the new potable line, and the applicant will bear the associated costs.

*4.8-2(c)* *Prior to commencement of initial mine dewatering, the Project Applicant shall implement the Well Mitigation Plan (February 2, 2021, Rise Grass Valley, Inc.) by connecting 30 properties in the East Bennett area to the NID potable water system (see Figure 1 and Table 1 of the Well Mitigation Plan for specific property locations). The Project Applicant shall be responsible for fully funding the following for each property connection:*

1) *Engineering and Permitting <u>to NID and County standards</u>.*
2) *Construction of main water piping, <u>interconnecting the existing NID pipelines at E. Bennet Road and Whispering Pines Lane in accordance with NID standards and NID approved engineering design.</u>*
3) *Construction of service lateral piping <u>in accordance with NID standards and NID approved engineering design.</u>*
4) *Installation of water meters at property line <u>in accordance with NID standards and NID approved engineering design.</u>*
5) *Connection of water meters to house (If requested and authorized by property owner)*

6) *Closure of domestic water wells (If requested and authorized by property owner)*

7) *NID installation and capacity charges for a 5/8-inch meter connection.*

8) *Reimbursement for water charges, for monthly fixed service charges and use of up to 400 gallons per day, will continue until the sooner of the following occurs: 1) The property is sold by the owner after the NID connection is accomplished and paid for by Rise. 2) The property is annexed into the City of Grass Valley.*

9) *Of the 30 properties, it is anticipated that only APN 009-600-012 is not eligible for water cost reimbursement as it is currently vacant. Existing NID customers will not be eligible for reimbursement of NID water charges and will be confirmed through consultation with NID during the design process.*

10) *All easements necessary for construction and ongoing maintenance of the new pipeline shall be acquired by the applicant and conveyed to NID prior to acceptance of the new potable line.*

*Proof of satisfaction of this measure shall be provided to Nevada County Environmental Health Department for each property identified in the Well Mitigation Plan.*

The above changes to Mitigation Measure 4.8-2(c) of the DEIR are for clarification purposes, in response to NID's comments, and do not alter the analysis, nor the conclusions of the DEIR.

## Response to Comment Agcy 10-2

The commenter states that the DEIR incorrectly requires the potable water pipeline to be constructed to County standards although NID has jurisdiction over the construction standards for the pipeline. However, page 3-36 of the DEIR discusses compliance with County guidelines for the purpose of standards applicable to disposing of asphalt and road paving, not the pipeline itself. Mitigation Measure 4.8-2(c) requires the connection to the NID potable water system, which would require engineering approval from NID and construction to the appropriate NID standards. As shown on the above response, the FEIR includes language clarifying that the potable water pipeline will be constructed to NID standards.

## Response to Comment Agcy 10-3

The Well Mitigation Plan has been revised to include the installation of Double Check Valves. Please see Appendix D to this Final EIR for a revised Well Mitigation Plan. As described in the Well Mitigation Plan (Appendix K.9 of the DEIR), the applicant will close property owners' wells, using certified well drillers operating under Nevada County regulations, if well closure is requested by the landowner at the time of NID connection and service to their properties. If a property owner decides to retain and continue using their water well, the cost of the well's operation, including Double Check Valve monthly fees, would be the owner's responsible and not the applicant.

## Response to Comment Agcy 10-4

The single-family home unit demand factor of 0.36 acre-feet per year per connection is used by NID for projecting demands. (Page 18 of the NID 2020 Urban Water Management Plan). This is equivalent to 321 gallons per day. The well mitigation plan proposes compensation of up to 400 gallons per day or approximately 25% more than NID's estimate of demand for a single-family

home. The water supply assessment uses a higher water consumption figure as a conservative measure to ensure adequate water supply; but this is not the appropriate figure to use for the Well Mitigation Plan.

## Response to Comment Agcy 10-5

The commenter states that the applicant should be required to conduct an extensive and robust well and groundwater monitoring effort prior to and during dewatering and should guarantee potable water for any well impacted beyond the 30 wells that are proposed to be connected to NID water supply. A rigorous Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). As described on page 4.8-66 of the DEIR, the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Mitigation Measure 4.8-2(b) requires that if, based on the GMP, it is determined that mining operations are resulting in a significant impact to any wells (including wells beyond the 30 wells included in the expected impact area), the Project Applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted.

Please also see Master Response 15 – Adequacy of Groundwater Monitoring Wells, for an updated description of the proposed monitoring approach, which now also includes a proposal by the applicant to monitor domestic water wells within or nearby the predicted 1-ft drawdown isopleth of the project. These 378 properties are listed in Table 1 and shown in Figure 1 of Master Response 15. To provide property owners additional assurance, a condition of approval will be imposed on the project requiring this domestic well monitoring.

## Response to Comment Agcy 10-6

The commenter states that the applicant should pay for water for any parcel connected to NID water supply for the life of the mine, even after the parcel is sold or annexed into the City of Grass Valley. The Well Mitigation Plan (Appendix K.9 of the DEIR) takes a conservative approach and presumes that an owner who decides to connect to the NID system has been impacted by and at the fault of the mining operation, even if no impact to groundwater well supply has occurred. As such, the Well Mitigation Plan was designed to be even more conservative than Nevada County General Plan Policy 17.12, which requires an impact as a prerequisite to the obligation to pay for water, which policy states “If it is determined that the operator is at fault, impacted owners shall be compensated by the operator.” A new homeowner would not be impacted because the impact would have previously occurred, and the cost of purchasing water from NID for that new homeowner would be the same as buying any other home connected to NID’s water supply. The provision of free water as a selling feature to a new buyer is not contemplated by the policy. If a property was annexed into the City of Grass Valley, it would be subject to the ordinances of the City which allows water wells to be used for irrigation purposes only (Grass Valley General Ordinance Section 13.16.020) and would therefore require a property owner to connect to the potable water supply and pay for their water use. As annexation of a home into the City would already require connection to NID water supply and purchase of NID water, continuation of payment for water by the applicant after annexation would be a windfall to the property owner rather than mitigation of an impact, and is not required by CEQA or County policy.

## Response to Comment Agcy 10-7

The commenter states that the applicant should conduct advance sampling of water quality and production for the wells located in the Woodrose, Greenhorn and Beaver Lane areas to establish a baseline. A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). As discussed on page 4.8-66 of the DEIR, the GMP will select locations of the

monitoring wells in order to provide spatial coverage throughout the project and adjacent areas and include collection of water quality data. As discussed on pages 2-3 of the GMP (Appendix K.8 of the EIR), assessment of impacts of water-level changes in domestic wells is difficult to perform when examining each domestic well on an individual basis because of operational and depth considerations for each well. As noted in Master Response 15, the applicant has also provided a Domestic Well Monitoring Plan to monitor domestic water wells, including water level and quality, within or nearby the predicted 1-ft drawdown isopleth of the project. These 378 properties are listed in Table 1 and shown in Figure 1 of Master Response 15. To provide property owners additional assurance, a condition of approval will be imposed on the project requiring this domestic well monitoring.

## Response to Comment Agcy 10-8

The commenter notes that the greenhouse gas emissions modelling for the project assumed that only 26 residences would be switched to NID water, while the Well Mitigation Plan requires up to 30 residences be connected to NID water. This discrepancy is due to the fact that four of the 30 properties along E. Bennett Road within the potential well impact area are already serviced by NID, as shown in Table 1 of the Well Mitigation Plan (Appendix K.9 of the DEIR). As four of the 30 parcels are already connected to NID water, no greenhouse gas emissions would be caused by the project for those four parcels. Indoor/outdoor water use for the homes along the potable water line and electricity intensity factors are based on California Emission Estimator Model (CalEEMod) defaults, as stated in the footnote on page 349 of Appendix E.1 of the EIR. An assumption of 26 dwellings for a total water demand of 2.76 million gallons (MG) of water per year results in average total water use of 291 gallons per day per dwelling. This is similar to the single-family home unit demand factor of 0.36 acre-feet per year (321 gallons per day) per connection used by NID for projecting demands. (Page 18 of the NID 2020 Urban Water Management Plan). The modelled GHG emissions for water supply to residences along E. Bennett Road are only 1.2 metric tons $CO_2e$ per year. A change in assumptions as suggested by the commenter is not warranted because the four parcels are already connected to NID water supply, and further the change would result in only a trivial increase in GHG emissions not relevant to the impact analysis.

## Response to Comment Agcy 10-9

The commenter states that the applicant should supply water to any wells that are impacted due to mine dewatering beyond the 30 parcels proposed for connection to NID water, and should also place monitoring wells near the Greenhorn, Woodrose and Beaver Lane areas. Further, the commenter requested that the monitoring well depth mirror the existing wells in the area. As discussed below, the applicant is required to replace water for any parcel that has significant impact to groundwater supply due to mine dewatering, and further, five monitoring well sites are planned in the vicinity of the Greenhorn, Woodrose, and Beaver Lane areas with shallow/deep well depths to capture water level fluctuations at all relevant depths.

A rigorous Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). The mitigation measure requires water-level monitoring data for a minimum of 12 months before commencement of dewatering of the mine. As described in Section 7.0 of the GMP (Appendix K.8 of the EIR), data loggers would collect water-level information once every 1 to 4 hours throughout the life of the project. As described on page 4.8-66 of the DEIR, the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Mitigation Measure 4.8-2(b) requires that if, based on the GMP, it is determined that mining operations are resulting in a significant impact to groundwater wells, the Project Applicant shall

be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted.

As described on page 4.8-66 of the DEIR the GMP will select locations of the monitoring wells in order to provide spatial coverage throughout the project and adjacent areas. As shown in Figure 1 of the GMP, five monitoring well sites are planned in the vicinity of the Greenhorn, Woodrose, and Beaver Lane areas. Section 4.0 of the GMP describes that each monitoring well location will consist of a shallow and a deep well installation. This "shallow/deep" pairing method is designed to assess changes in vertical water levels and gradients that may occur as the result of mining activities. Shallow monitoring wells will be installed to depths of approximately 100 ft, and deep monitoring wells will be installed to depths of approximately 300 ft. The exact installation depths will vary between each well pair and will be determined based on observed groundwater conditions during the field installation activities.

As noted in Master Response 15, the applicant has also provided a Domestic Well Monitoring Plan to monitor domestic water wells, including water level and quality, within or nearby the predicted 1-ft drawdown isopleth of the project. These 378 properties are listed in Table 1 and shown in Figure 1 of Master Response 15. To provide property owners additional assurance, a condition of approval will be imposed on the project requiring this domestic well monitoring.

## Response to Comment Agcy 10-10

The commenter asserts that the applicant should be required to provide financial assurance of 14 million dollars to cover the cost of mitigating dewatering impacts in the Greenhorn, Woodrose and Beaver Lane areas. As discussed below, a bond for construction of water supply infrastructure in this area is not necessary because no significant impacts to domestic water wells are predicted in the Greenhorn, Woodrose, and Beaver areas. Moreover, the well monitoring program, required as mitigation for the project would provide early warning of any potential dewatering impacts to the Greenhorn, Woodrose and Beaver Lane areas, allowing the mine operator to provide replacement water prior to impacts, or to slow or halt dewatering to prevent any impact prior to water supply being connected.

The analysis provided in Section 4.8-2 of the DEIR concludes that the proposed mining operations could result in adverse effects to seven domestic water supply wells in the East Bennett area during the life of the mining operation. Pursuant to Nevada County General Plan Policy 17.12, the project would address this by installing a potable water supply line in East Bennett Road and providing individual well owners with a connection to the potable water line. No significant impacts to domestic water wells are predicted in the Greenhorn, Woodrose, and Beaver areas, as drawdown in these areas is not expected to result in a 10% or greater reduction in groundwater well column levels (See Sections 4.2.2.1, 4.2.2.2, and 4.2.2.3 of Appendix K.2 of the DEIR). The predictions include the use of a 100% safety factor, multiple sensitivity scenarios, and have been peer reviewed by the County's independent expert consultant. However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies.

A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). Please refer to Chapter 4 of this Final EIR, Mitigation Monitoring and Reporting Program, which includes a table containing all of the mitigation measures required in the DEIR. As described on page 4.8-66 of the DEIR, the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented.

As stated in Section 3.0 of the GMP, the dewatering of the existing mine workings, prior to the commencement of actual mining, is analogous to a largescale pumping test that is a common tool in the field of hydrogeology to assess how drawdowns in the water-bearing zones. Monitoring wells in closer proximity to the mine will generally experience drawdowns before wells farther away. The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented.

Mitigation Measure 4.8-2(a) requires that a projected water-level impact assessment for individual domestic wells shall be performed once dewatering of the underground mine workings commences, based on responses of the measured groundwater levels of the project monitoring wells. The projected groundwater drawdown shall be estimated for each domestic well in the project area. This impact assessment shall be performed by tabulating the variation of the measured water levels from the project monitoring wells over the monitoring period and during the dewatering of the underground mine workings and mining operations. For each domestic well, a projected and seasonally averaged water level shall be estimated based on the domestic well location and the background potentiometric conditions, which will serve as a baseline groundwater level and shall be developed prior to the initiation of dewatering of the underground mine workings. To provide property owners additional assurance regarding impacts of mine dewatering, a condition of approval will be imposed on the project requiring that monitoring of domestic water wells will be conducted upon request by property owners within or nearby the predicted 1-ft drawdown isopleth of the project (See Master Response 15 - Adequacy of Groundwater Monitoring & Mitigation).

If the water level impact assessment showed a potential impact to wells outside of the East Bennett area, assuming the 100% safety factor, the applicant would be required to mitigate this impact before it occurs in accordance with Mitigation Measure 4.8-2(b). The mitigation would be for properties which may be potentially impacted as determined in the projected water-level impact assessment. As discussed in the Well Mitigation Plan, if a dewatering impact to an area outside of the E. Bennett area were projected during operations, pre-emptive action would be taken as necessary to ensure immediate water supply and compensation. The 10% drawdown threshold of significance is extremely conservative and, in most cases, would not lower the water level below the casing of the domestic well. Therefore, well mitigation may not be required after inspection. If reduction of the water column was great enough to reduce the well's yield, a simple adjustment to the pumping system may only be required. For example, by pumping at a lessor rate over a longer duration and if necessary, installing or increasing the size of a pressure or holding tank. In the unlikely case where these measures were not sufficient, appropriate mitigation could be the deepening of a single well, drilling of a new well, or the provision of potable water service to a group of wells. Slowing or halting of mine dewatering could be done as necessary to allow enough time to complete mitigations. In the case of deepening a well this may be several weeks and would require a simple well construction permit from the Nevada County Environmental Health Department and the mobilization of a licensed contractor. Several months may be required in the case of connecting a group of wells to the NID system. NID recently completed the Loma Rica District Waterline Extension project in approximately 3 months, which involved the installation of 3,000 feet of 8-inch diameter treated waterline to 20 parcels. A notice of exemption from CEQA was filed on July 21, 2021. Construction commenced in early October 2021 and was completed and operations on December 10th, 2021. https://www.nidwater.com/loma-rica-district-financed-waterline-extension-project

The Well Mitigation Plan (Appendix D to this Final EIR) has been modified to clarify the actions that would be taken as described above.

In addition, as noted in Master Response 15, the applicant has also provided a Domestic Well Monitoring Plan to monitor domestic water wells, including water level and quality, within or nearby the predicted 1-ft drawdown isopleth of the project. These 378 properties are listed in Table 1 and shown in Figure 1 of Master Response 15. To provide property owners additional assurance, a condition of approval will be imposed on the project requiring this domestic well monitoring.

## Response to Comment Agcy 10-11

The commenter requests real-time flow data for the discharge of water into South Fork Wolf Creek, via a publicly accessible webpage that shows one week of flow history. Additionally, NID requests one week of notice whenever a planned outage in treatment or other interruption to discharge flow is expected.

Pursuant to the commenter's request, the applicant will be required to provide one-week notice of any expected flow interruptions when feasible, and notice of any spill or contaminating event via a condition of approval. Additionally, the applicant will be required to provide NID access to real-time flow data of South Fork Wolf Creek directly downstream from the project's discharge, with 15-minute interval data, with a trend history of at least one week, per a condition of approval. The County will not require the flow data to be publicly available, but the data may be made publicly available at the applicant's or NID's discretion.

## Response to Comment Agcy 10-12

The commenter requests that a mitigation measure be added to ensure the volume of mine discharge water to South Fork Wolf Creek will not limit storm flow capacity during storm events. and notes that historic flows through the Property have been up to 35 CFS. As discussed in Section 4.8-3 of the DEIR, the detention basin for the Brunswick Industrial Site is sized to detain storm flows to compensate for the quantity of treated mine water discharged to South Fork Wolf Creek, in addition to compensating for increased runoff from potential future industrial development of the site.

Mitigation Measure 4.8-3 requires the applicant to submit a Final Drainage Report to the Nevada County Planning Department for review and approval. The Final Drainage Report shall demonstrate that the on-site storm drain systems are sized such that site runoff (in addition to treated mine discharge for the Brunswick Industrial Site) under the post-development condition will not exceed pre-development levels in the downstream channel(s) during the design storm events. As such, the DEIR already includes mitigation that ensures NID's ability to discharge water through the Property during storm events will not be limited; thus, no additional mitigation is required.

## Response to Comment Agcy 10-13

Backflow prevention devices will be installed pursuant to NID rules (See Section 9 of Nevada Irrigation Water Service Regulations[7]) at the Brunswick and Centennial sites. Engineering details would be provided in the submittal of Improvement Plans to Nevada County, which require County review to ensure compliance with NID rules and County approval before commencement of construction.

Re: Revised Comments on Draft EIR for Idaho-Maryland Mine, Nevada County, CA

**Introduction**

**Agcy 11-1** The Northern Sierra Air Quality Management District (NSAQMD) has been involved at various stages with the development of the environmental documentation for this proposed project. As a responsible agency under the California Environmental Quality Act, the NSAQMD neither supports nor opposes this project, and is submitting these comments in the interest of ensuring the adequacy of the DEIR. The NSAQMD recognizes that the commitment to use electric underground mobile equipment instead of diesel-powered equipment is a significant mitigation.

**Asbestos Emissions**

The Air Quality sections of the DEIR include a newly introduced concept of converting asbestos measurements to PCM (phase contrast microscopy) units.

**Agcy 11-2** During the DEIR comment period the NSAQMD contacted OEHHA with questions about the asbestos PCM conversion process. OEHHA staff referred the NSAQMD to the California Air Resources Board's (CARB) Risk Analysis Section, which worked with CARB's Monitoring and Laboratory Division in providing an assessment of the underlying science. CARB staff concluded that "it is not appropriate to determine risk from rock samples" (personal communication with CARB staff, 3/28/22) and noted that the PCM conversion factor was developed for air monitoring samples, not rocks. For reference, the origin of the PCM conversion factor is EPA's Airborne Asbestos Health Assessment Update (EPA/600/8-84/003F, 1986). Since there is no approved method for calculating risk from rock samples, comparison with the NSAQMD's AB2588 toxics significance threshold based on rock composition carries some uncertainty.

**Agcy 11-3** The DEIR is correct in observing that the Asbestos Airborne Toxic Control Measures (ATCMs) at CCR Title 17, Section 93105 and 93106 apply to the project. Underground mining is not covered in the ATCMs, but will be subject to permit conditions prescribed by the NSAQMD via the required Authority to Construct/Permit to Operate.

**Agcy 11-4** Note that the footnote on page 55 reads, "Samples containing naturally-occurring asbestos were from underground rock only..." whereas November 2021 TEM sampling did discover asbestos in one of the two surface samples (#Y962843) from the 55-acre Centennial site.

1

Also, there appears to be at least one mistake in the TEM lab reports. The sheet for sample #Y962990 lists a "Calculated Asbestos Concentration (Weight %)" for chrysotile asbestos as .075%; there is an apparent laboratory error in reporting the total as <0.001 %.

**Criteria Pollutant Emissions**

**Agcy 11-5** On page 304 of Appendix E.1, there are multiple tables that require explanation. The rationale for using a silt content of 1.6% for the crushed rock and a moisture content of 15% for the sand tailings should be discussed. The normal ranges noted in AP-42 section 13.2.4 are a silt content of 0.44% to 19% and a moisture content of 0.25% to 4.8%.

**Agcy 11-6** Additional assumptions on document page 304 require explanation, including a wind erosion area of 0.72 acres, 0.34 acres of access road and 1.00 acre either seeded or with covering underway. Elsewhere in the DEIR, it appears that more surface is to be disturbed than the area indicated in these assumptions. Likewise, the assumptions for bulldozing and compaction (2.43 hrs/day and 1.02 hrs/day respectively) appear less than indicated elsewhere in the DEIR.

**Agcy 11-7** The Logging and Chipping (described on page 4.3-56) is assumed to be for 24 total acres (Centennial and Brunswick sites combined). We see no mention of emissions associated with ongoing vegetation management.

**Agcy 11-8** The beginning of the Earthwork and Material Handling section (App. E-1, p. 24) reads, "The barren rock will be transported from the concrete silo using a series of chutes and conveyors to a fully enclosed truck loading building." Each transfer point along the "series of chutes and conveyors" is an emission point which is not accounted for in the DEIR.

**Agcy 11-9** Table 2 of the Health Risk Assessment lists the Base Elevation for the generators and diesel storage tanks in meters (placing them above 9,000'), whereas it should be feet. The calculations require verification to ensure that the modeling inputs are in the correct units.

**Agcy 11-10** The footnote for table 8 on page 28 of E.1 says, "Concentrate truck trip distance of 145 miles is based on the distance between the project sites and the Port of Oakland." An explanation of why the ore concentrate is going to the Port of Oakland is necessary. If it is being transported to a refinery elsewhere, the associated emissions should be included in the GHG analysis since GHG emissions are a global concern.

**Agcy 11-11** Unnumbered document page 184 of E.1 (for paved road fugitive emissions from vehicles) shows a table that has fractions of vehicles making fractions of trips, and then rounds the resulting VMT numbers before performing the final calculations. For instance, Freight Trucks have an average of 0.43 daily trips going 0.52 miles and lists their VMT as 0. The 0 miles travelled is then multiplied by the weight of the trucks, which yields 0 pounds. It also shows 1 concentrate truck trip per day, whereas in some places there are 10 concentrate trips/day and there are 5 concentrate truck trips listed on page 186 and 187. This is an example of how not only concentrate trucks but also other vehicles display different mileage, different trip numbers, etc. throughout the emissions calculations. These require standardization and accurate data conclusions.

| | |
|---|---|
| **Agcy 11-12** | The emissions estimates assume that all on-site roads will be paved. This requires inclusion as a condition or mitigation measure. |
| **Agcy 11-13** | The spreading of 1,000 tons per day of engineered fill with a dozer require inclusion in the off-road equipment emissions (dozers are considered to be off-road equipment) data. |
| **Agcy 11-14** | App. E-1, document page 380/1938 lists 3 diesel generators that are proposed to operate 8 hours per day, 7 days per week in perpetuity (operational). The emissions from these generators require inclusion in the various emission quantification tables. Similarly, Table 4 (off-road construction emissions) of App. E.1, p. 21 includes 9 portable diesel generators operating 6 hours/day, 6 days/week that require inclusion in the emissions estimate data columns. |
| **Agcy 11-15** | Emissions from construction of the septic leach field and sewage line running up hill to the septic system require inclusion in the emissions analysis. Emissions from any backup diesel generator(s) required to pump sewage up the hill require inclusion in the emissions data. |
| **Agcy 11-16** | The OFFROAD model does not include fugitive emissions. It only includes engine emissions. The Operational Off-road Equipment list (App. E-1, document page 380/1938) lists off-road equipment at the Brunswick site. PM emissions from those require addition to the TAC calculations, which specify zero emissions from off-road equipment. |
| **Agcy 11-17** | The "Earthwork and Material Handling Fugitive Dust" section starting on page 300 includes limited construction activities that are anticipated (SF Creek Culvert Replacement, Pond Berm Repair, Service Shaft Collar and Building Pad). It assumes a serpentinite content in fill of 14.3%, with an asbestos content of 0.20%. A figure of 0.03% (which requires explanation) is derived from these numbers. There is a calculation of wind erosion that assumes a disturbed area of 4 acres. The resultant calculated fugitive dust emissions from wind erosion during construction is 0.41 tpy of PM10 and 0.02 tpy of PM2.5. The following unnumbered page (doc page 301) has an unlabeled table which indicates that only 40,150 tons of fill would be placed per year (versus the proposed 365,000 tpy). The content of the pages after that require clarification. For example, there is a sub-table called "Compaction" as part of the Fill Placement calculation series that notes a piece of equipment ("Cat563") that works for 0.06 hours (216 seconds) per day. On that same page is a bulldozer that moves 411.1 tons per hour and works 0.27 hours (16 minutes and 12 seconds) per day. |
| **Agcy 11-18** | The reason for selecting 25 meters as the plume height and width for all of the line volume sources in Table 2 starting on page 8 of Appendix B of Appendix E.1 require explanation. |
| **Agcy 11-19** | The DEIR cites AP-42, Ch. 13.3 as a source for blasting emissions information. ANFO is listed in that source as emitting 17 lbs./ton of NOx. At 0.93 tpd of ANFO, that calculates to 2.89 tons per year of NOx emissions from ANFO detonation. Nitrogen oxides are principally NO2, which is recognized as a non-carcinogenic TAC. These TAC emissions are excluded from the DEIR. The "Underground Blasting and Crushing" section (p. 4.3-56) assumes no TAC emissions from blasting. |

**Agcy 11-20**

**ASUR Plan**

The NSAQMD will take the ASUR Plan into consideration while developing an Authority to Construct/Permit to Operate.

Sincerely,

Gretchen Bennitt

Gretchen Bennitt, APCO
Northern Sierra Air Quality Management District

## AGENCY LETTER 11: GRETCHEN BENNITT, NORTHERN SIERRA AIR QUALITY MANAGEMENT DISTRICT

### Response to Comment Agcy 11-1

The County acknowledges the comment as an introduction to comments that follow. This comment is included in the Final EIR for review and consideration by the decision-makers prior to a final decision on the project. No further response is required or necessary.

### Response to Comment Agcy 11-2

The Northern Sierra Air Quality Management District (NSAQMD) has indicated that there is no approved method, and thus some uncertainty, regarding the estimation of asbestos risk based on rock samples. Based on this lack of methodology and associated uncertainty, compliance with the California Air Resources Board (CARB) Air Toxics Control Measures (ATCMs) for naturally occurring asbestos, including development of an Asbestos Dust Mitigation Plan (ADMP), is the standard approach within CEQA documents to address health concerns associated with exposure to asbestos from unpaved surfaces, construction and grading operations and quarries where asbestos is found or likely to be found in order to ensure potential health risk impacts to the public would be minimized to a less than significant impact. Multiple other projects in the NSAQMD jurisdiction, as well as throughout the state, have relied upon compliance with these naturally occurring asbestos ATCMs in order to control any potential asbestos emissions to the extent possible. As described in Mitigation Measure 4.3-2 of the DEIR, the proposed project shall also comply with all applicable criteria in the CARB ATCMs for naturally occurring asbestos, which would result in a less than significant impact. However, based on public concern regarding asbestos exposure, and to provide the most information possible regarding potential health risk, the DEIR included quantitative analysis of asbestos risk based on a very conservative methodology (as described below and in Master Response 22 – Conservatism of Asbestos Assumptions).

The Health Risk Assessment for the project uses modeled air concentrations to estimate health risks from asbestos emissions based on the Office of Environmental Health Hazards Assessment's (OEHHA) *Air Toxics Hot Spots Program Risk Assessment Guidelines – Guidance Manual for Preparation of Health Risk Assessments* (2015) (OEHHA Guidelines). The modeling of asbestos air emissions from operations (such as blasting, rock handling, and grading) is done in the same manner as other toxic air contaminants (TAC) contained in rock (such as metals or silica) but uses the appropriate base units of TAC content required for asbestos (TEM asbestos structures). The modeling performed for the Health Risk Assessment was generally completed as follows:

1. Dust emission rates ($PM_{10}$) from various project activities were estimated
2. Dust concentrations were modeled at locations surrounding the project using air dispersion modelling
3. The asbestos content of dust was estimated using the most conservative approach, using the maximum content of asbestos structures in rock and sand tailings and assuming all asbestos structures are liberated from dust particles. This is a very conservative assumption. Please see also Master Response 22 – Conservatism of Asbestos Assumptions
4. The health risk at receptor locations was estimated based on the modeled concentration of airborne asbestos fibers in accordance with the OEHHA Guidelines.

The base unit for asbestos content in rock is TEM structures per unit mass. The model accounts for the liberation of the asbestos TEM structures into the air though dust creation and dispersion. The TEM structures then must be converted to equivalent PCM fibers in order to calculate the health risk at a receptor location. The OEHHA Guidelines provide a conversion factor to convert PCM fibers to mass (0.003 µg = 100 asbestos fibers PCM). The use of PCM equivalent weight percent is for convenience in modeling because all other TACs are modeled in weight percent and asbestos is reported in units of pounds per year under the Air Toxics Hot Spots Program (OEHHA 2015 Appendix C). PCM equivalent weight percent of rock are interchangeable with TEM structures per unit mass and have no effect on the modeled health risk for asbestos.

As stated on page 4.3-42 of the EIR, the NSAQMD's cancer and noncancer thresholds to assess health risk significance for CEQA are consistent with what are used for the AB 2588 risk assessment procedures. The threshold of significance for health risk is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concluded that the health risk to the most sensitive receptor will be below this threshold.

Nevertheless, the DEIR concluded that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and required mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an ADMP to the NSAQMD for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring to ensure that project asbestos emissions meet all applicable standards.

## Response to Comment Agcy 11-3

The NSAQMD confirmed that the DEIR was correct that the Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations and ATCM for Surfacing will apply to the project. Comment noted. Notably, the Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations defines a Quarry as a facility or operation that obtains stone from the earth by means of cutting, digging, excavating, or blasting. Underground mining would be captured under this broad definition.

## Response to Comment Agcy 11-4

The NSAQMD noted that the footnote on page 55 had an error in it. Therefore, footnote 41 has been deleted and the body text on page 4.3-80 of the EIR has been revised as follows (additions in underline, deletions in ~~strike-out~~):

> Because asbestos was found to be present in some of the ~~underground mining~~ material samples that Rise Grass Valley Inc. sent for laboratory analysis,~~[41]~~ an ADMP is required to be implemented to reduce potential asbestos exposure and protect public health.
>
> ~~41. Samples containing naturally-occurring asbestos were from underground rock only; naturally-occurring asbestosis not known to outcrop at the surface of the Brunswick Indutrial Site or Centennial Industrial Site.~~

The error in the TEM lab report is also noted. This error does not affect the analysis of asbestos emissions from the project, as the correct value was used in the analysis.

## Response to Comment Agcy 11-5

The silt content for crushed barren rock was assumed at 1.6% based on EPA AP-42 Table 13.2.4-1 mean value for crushed limestone for the stone quarrying and processing industry. Other values presented in this table are from iron and steel production, taconite mining, and coal mining. The

stone quarrying industry is most similar to the proposed project's production of barren rock and therefore the selection of this silt content is appropriate.

A moisture content of 15% was assumed for sand tailings based on the estimated moisture content of sand tailings after dewatering by filter press. Typical moisture in filter cake for mineral tailings for pressure filters would range from 15% to 20% (Please see Table 6.43 of Metso Mineral Processing Handbook Edition 12)[8]. Therefore, the use of 15% is the most conservative assumption for estimating fugitive dust emissions, as a higher moisture content assumption would reduce the fugitive dust generation.

## Response to Comment Agcy 11-6

The commenter questions the disturbance area assumptions used in the air quality model. The area worked was determined from an assumed compacted lift thickness and fill density provided by NV5 in the geotechnical reports for the project. The resulting tonnage of a single 0.5-foot (6 inch) lift is calculated at 1,388 tons per acre. At the daily tonnage of 1,000 tons per day this would equal an area worked of 0.72 acres per day. For conservatism, it was assumed that only a single lift would be placed in a day and the entire area exposed to wind erosion. In reality, multiple lifts might be placed during a day with a smaller overall exposed surface area. The 0.34-acre area of the access road is assumed from a road length of 1,000 feet and a road width of 15 feet, which is a conservative assumption of road length based on the expected project site configuration.

Bulldozing and compaction productivity were estimated from the Caterpillar Performance Handbook.[9] The compacted thickness of lift and number of compaction passes are provided by NV5 in the geotechnical reports for the project. The hours of bulldozing and compaction were more refined in the fugitive dust analysis in order to accurately estimate the fugitive dust generated from placement and compaction or engineered fill, but do not underestimate the likely work hours for these activities. Of note, the air quality analysis assumes a greater amount of operating hours per day for the calculation of exhaust criteria air pollutants and diesel particulate matter, and therefore exhaust emissions from bulldozers and compactors are overstated in the DEIR. This conservatism in exhaust emissions does not affect the analysis or conclusion of the DEIR.

## Response to Comment Agcy 11-7

The logging and chipping would remove existing forest vegetation where engineered fill is proposed to be placed. The emissions from the logging and chipping activities were included in the air quality emissions analysis. The slopes of the fill pile will be seeded with grass and this grass would be cut periodically (to 4-inch height as stated on page 4.13-20 of the DEIR). However, any emissions from grass mowing would be negligible and would not change the results of the analysis.

## Response to Comment Agcy 11-8

The emissions associated with the transfer points along the series of chutes and conveyors are presented in the second to last row of the table "Underground Mining – Stationary" on page 294 of Appendix E.1 labelled "Transfer to 500 ton barren rock silo" and the first two rows of the table "Ore Processing – Surface" on page 195 of Appendix E.1 labelled "Transfer to conveyor" and "Transfer to haul trucks".

[9] Caterpillar Performance Handbook 48, available at: https://wheelercat.com/wp-content/uploads/2018/07/SEBD0351_ED48.pdf

## Response to Comment Agcy 11-9

The base elevation for the generators (STCK8) and diesel storage tanks (STCK9 and STCK10) in Table 2 of the Health Risk Assessment are shown in feet, but the unit notation is in meters. This notation is a typographical error in the table. The correct elevation for these sources was used in the model as confirmed on page 395 of Appendix E.1, with the elevation of these sources noted at 837.71 meters, 838.73 meters, and 759.39 meters.

## Response to Comment Agcy 11-10

The Port of Oakland is the principal ocean gateway for international containerized cargo shipments in Northern California. The Union Pacific and BNSF railroad facilities are located adjacent to the marine terminal area. Gold concentrate would be purchased by third parties and loaded into containers for shipment overseas or by rail to destinations in North America. Alternatively, the material could be trucked to Nevada State where processing facilities owned by third parties exist. However, the distance to the Nevada State border from the project site of approximately 90 miles is less than the distance to the Port of Oakland of 145 miles, so the Port was selected to provide a more conservative estimate of emissions.

The commentator suggests that GHG emissions associated with the international or interstate shipment of concentrates should have been included in the DEIR. This transport would be considered part of a lifecycle analysis. The California Natural Resources Agency, in adopting the CEQA Guidelines Amendments on GHG emissions, found that lifecycle analysis was not warranted for project-specific CEQA analysis in most situations, for a variety of reasons, including lack of control over some sources, and the possibility of double-counting emissions (see Final Statement of Reasons for Regulatory Action, December 2009). The gold concentrates produced by the project would be purchased by a third party and refined at a location that is not known and not in the control of the project. Calculation of GHG emissions from third party transport of gold concentrate would be speculative and therefore not required under CEQA. Please see also Master Response 26 – Lifecycle GHG Emissions.

## Response to Comment Agcy 11-11

The purpose of the table on page 184 of Appendix E.1 is to calculate the weighted average vehicle weights of equipment and trucks along on-site paved roads only. Thus, the VMT values in question only pertain to on-site travel and do not factor into the off-site assumptions, which seems to be the distinction that the commenter was unclear about. A different calculation was used for off-site vehicle travel, which resulted in the difference in assumptions identified by the commenter. This on-site only estimate was used to determine the pounds per VMT for fugitive dust entrainment along paved roads based on the project-specific vehicle mix, which resulted in a more conservative value for particulate emission factors (since the majority of vehicles on-site are heavy trucks and equipment) than for off-site roadways, which have passenger vehicles as the primary proportion in the vehicle mix.

In addition, the table in question depicts only whole numbers for the “Total Vehicle Miles Traveled”, so values less than 1 are not shown. However, the equations do factor in the fractional “Total Miles Traveled” for the various trucks. For instance, although the table shows “0” total VMT for Freight Trucks, the equation of “Average Daily Trips” multiplied by “Total Distance (miles)” resulted in the following: 0.43 * 0.52 = 0.22 total VMT on-site, which was factored into the estimate of the weighted average on-site vehicle weights, and thus the pounds of particulate matter per VMT emission factor. The same table with the increased decimal places for “Total Vehicle Miles Traveled” is shown below for clarification:

| Vehicle | Average Daily Trips | Total Distance (miles) | Total Vehicle Miles Traveled | Weight (tons) |
|---|---|---|---|---|
| Haul Trucks | 50 | 0.59 | 29.50 | 20.8 |
| Freight Trucks | 0.43 | 0.52 | 0.22 | 27.5 |
| Concentrate Trucks | 1.0 | 0.52 | 0.52 | 27.5 |
| Explosives Trucks | 0.14 | 0.52 | 0.07 | 27.5 |
| Fuel Trucks | 0.15 | 0.52 | 0.08 | 27.5 |
| Cement Trucks | 1.28 | 0.52 | 0.66 | 27.5 |
| Outside Services (light vehicles) | 3.0 | 0.52 | 1.54 | 12.5 |
| Light Trucks | 80 | 0.52 | 41.21 | 3.45 |
| Employee Vehicles | 325 | 0.12 | 38.18 | 2.25 |
| Forklifts | | | 60.00 | 5 |
| Wheel Loader | 150 | 0.05 | 7.39 | 33 |
| **Weighted Average** | | | **179.37** | **8.1** |

## Response to Comment Agcy 11-12

The paving of all on-site roads in included in the Project Description and therefore a condition of approval or mitigation measure is not required. Please see Figure 3.8 of the EIR. Nonetheless, the air quality analysis did conservatively include some dust emissions from unpaved access roads, even though the roads are proposed to be paved. Please see also page 303 of the Appendix E.1.

## Response to Comment Agcy 11-13

The commenter states that a dozer is needed in the analysis to account for the spreading of engineered fill. Notably, a dozer is already included in the off-road equipment list and the associated emissions are included in the criteria air pollutant, TAC, and GHG inventories of the DEIR. Please see page 131 of Appendix E.1, which identifies a dozer for fill placement at the Centennial and Brunswick Sites.

## Response to Comment Agcy 11-14

Portable generators/welders are included in the off-road equipment lists for construction and operations and the associated emissions are included in the criteria air pollutant, TAC, and GHG inventories of the DEIR. Please see pages 131 through 135 of Appendix E.1, which identifies the pieces of equipment assumed for the various phases of project construction and operations.

## Response to Comment Agcy 11-15

Emissions from the construction of the septic leach field and sewage pipe is included in the grading and paving phase of the construction emissions in Appendix E.1 of the DEIR. The electricity demand for sewage treatment and pumping is included in the estimated electrical power consumption under the category “Water Treatment” on page 347 of Appendix E.1. As stated on page 4.3-104 of the DEIR, the use of backup generators during power outages is speculative and therefore the emissions for back-up power generators during outages are not included in the emissions estimates.

## Response to Comment Agcy 11-16

The $PM_{10}$ emissions from various off-road equipment in the OFFROAD model are used as a surrogate for diesel particulate matter (DPM) exhaust and are already incorporated into the Health Risk Assessment, as identified in Table 10 (“Off-Road Equipment” rows, “DPM” column) on page

386 of Appendix E.1. TACs in fugitive dust ($PM_{10}$) are not included in the OFFROAD model emission factors. TACs in fugitive dust (asbestos, silica, and metals) are included in the Health Risk Assessment and the assumptions discussed on 21-23 of the Health Risk Assessment.

## Response to Comment Agcy 11-17

The pages that the commenter referred to are for the grading during construction of the project (Year 2021) and not for the operations. The 40,150 tons of fill being moved is the historic fill that is currently on the Brunswick site. This material would be excavated, moved, and compacted on the site in order to create the planned site grading.

Bulldozing and compaction productivity were estimated from the Caterpillar Performance Handbook. The compacted thickness of lift and number of compaction passes are provided by NV5 in the geotechnical reports for the project. As shown on page 301 of Appendix E.1, bulldozing and compaction are assumed to average 110 tons per day. Given the small daily production and high productivity, the average hours per day are 0.27 hours per day bulldozing and 0.06 hours per day compaction. The disturbed area of 4 acres is the assumption of the maximum area of the site that would be actively graded at one time. As grading of areas is completed, the concrete foundations of buildings and asphalt paving would be completed which limits the area of disturbance exposed to wind erosion.

A Phase I-II Environmental Site Assessment (ESA) was conducted at the Brunswick site (Appendix J of the DEIR). There is currently historic mine fill on the site, some of which will be moved during site construction. Eight of fourteen trenches in the mine waste noted some serpentinite in the geological logs. A conservative assumption was made that 25% of the material in the trenches is composed of serpentinite. Therefore, a serpentinite content of 14% was assumed (8 ÷ 14 x 25%). Five of the trenches were tested for asbestos in previous environmental studies as described in the ESA. Three samples were determined to have no asbestos and two samples were determined to have asbestos but below the detection limit of 1%. Therefore, an asbestos content of 0.2% was assumed for serpentinite (Average of 3 samples with no asbestos and 2 samples at half detection limit). No conversion to PCM equivalent was made for the assumed asbestos in construction grading for the Health Risk Assessment. These asbestos assumptions are conservative and likely overstate the health risk during construction grading. Even with this conservatism, the Health Risk Assessment prepared for the project concluded that the health risk to the most sensitive receptor will be below the applicable cancer and non-cancer risk thresholds. Nevertheless, the DEIR concluded that the project would result in a potentially significant impact with respect to exposing receptors to substantial concentrations of asbestos and required mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the EIR requires the submission of an ADMP to the NSAQMD for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring to ensure compliance with all applicable standards.

## Response to Comment Agcy 11-18

This comment requests clarification on the source parameters in Table 2 of Appendix B of Appendix E.1. All references for the source parameters provided in Table 2 are shown in the footnote of that table as well as Section 7, References of the cited document. The NSAQMD does not have published guidance for air dispersion modeling. As such, nearby jurisdictions were evaluated for similar guidance to use for modeling. The Sacramento Metropolitan Air Quality Management District (SMAQMD) is the closest air district to the NSAQMD with applicable dispersion modeling guidance. In Section 2.2 of the SMAQMD Dispersion Modeling of

Construction Generated $PM_{10}$ Emissions document, emissions from exhaust should be modeled as volume sources with a release height of 5.0 meters and the lateral length in both directions being equal. The guidance also states that at least 50% of the project site area should be covered by the volume sources. The guidance omits any discussion on size of the lateral length of the volume sources. As such, Dudek consulted with various air districts throughout the State regarding the lateral dimension for volume sources. No published air district guidance in the State recommended a volume source lateral dimension. When discussing this issue with various air districts, the consensus was to have a volume source no greater than 25 meters in any direction when covering a site.

## Response to Comment Agcy 11-19

The commenter asserts that blasting emissions, in particular nitrogen oxides, were not included in the DEIR's analysis; however, these emissions were included in the analysis of criteria air pollutants. NOx is a criteria air pollutant and has been analyzed as such. As discussed on page 4.3-41 of the EIR, the NSAQMD established thresholds of significance for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because an AAQS is based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse effects to human health related to criteria pollutant emissions. $NO_2$ only has an acute reference exposure level, so no cancer or chronic non-cancer health effects are associated with exposure. To account for NOx in the health risk estimates, the assessment was rerun to include $NO_2$ and the resultant acute non-cancer health impacts of the project increased from 0.004 to 0.1, which is far below the significance threshold of 1. Please see Dudek Health Risk Assessment Memorandum for the Idaho-Maryland Mine Project – Hexavalent Chromium and Nitrogen Dioxide attached to the Final EIR. Therefore, there would be no change to the less than significant impact conclusion from the DEIR with respect to health risk.

## Response to Comment Agcy 11-20

The County acknowledges the comment and notes that it does not raise new or additional environmental issues concerning the adequacy of the DEIR. Comment noted.

Re: Comments on Draft EIR for Idaho-Maryland Mine, Nevada County, CA

**Introduction**

Agcy 12-1

The NSAQMD submitted comments and recommendations regarding the proposed project as part of the NOA/NOP, but these were omitted from the DEIR's NOP comment section.

The NSAQMD recommended that the applicant work with the Department of Toxic Substances Control, the US Geological Survey and/or the Office of Environmental Health Hazard Assessment to obtain concurrence that asbestos testing for the proposed mine is adequately addressed with regard to the number and locations of samples and applicable analytical techniques. It does not appear as if this was done.

The NSAQMD has also submitted additional comments and been involved in other ways with the environmental documentation process for the proposed project. Many of the NSAQMD's comments and observations have been addressed, but some important ones remain unaddressed. Notably, the DEIR includes a newly added, previously undiscussed method of converting asbestos in rocks to asbestos in air that is not backed by science.

Asbestos emissions are the primary concern of the Northern Sierra Air Quality Management District (NSAQMD). The DEIR's treatment of naturally occurring asbestos is scientifically unsound and therefore not adequate for CEQA purposes. Laboratory testing in November 2021 of seven dominant types of rock from the site discovered asbestos in every type, with an average of 594,625,000 asbestos fibers per gram. For perspective, a new penny weighs 2.5 grams. Based on the recent tests of 40 rock samples and 2 previous rock samples, in a penny's mass of average mine rock there are well over a billion asbestos fibers.

**Asbestos and Public Health**

Asbestos is a well-known carcinogenic toxic air contaminant. Effects of asbestos exposure are insidious, highly variable and may not show up for 10 to 40 years or more. The most infamous result of asbestos exposure is mesothelioma, a specific type of cancer. The Office of Environmental Health Hazard Assessment (OEHHA) approach to asbestos risk assessment under AB2588 (the Air Toxics Hot Spots Act) is currently based only on a person's risk of developing mesothelioma. It does not provide any assessment of risk of developing other types of asbestos-related diseases such as asbestosis (an inflammatory condition affecting the lungs that can cause shortness of breath, coughing, and permanent lung damage), pleural

plaques (changes in the membranes surrounding the lung), pleural thickening, benign pleural effusions (abnormal collections of fluid between the thin layers of tissue lining the lungs and the wall of the chest cavity) and assorted cancers of the lung, larynx, pharynx, stomach, colorectum and ovary.

For additional information on the effects of asbestos exposure, see the National Cancer Institute website (https://www.cancer.gov/about-cancer/causes-prevention/risk/substances/asbestos/asbestos-fact-sheet). Following is a relevant excerpt from this website:

*There is some evidence that family members of workers heavily exposed to asbestos face an increased risk of developing mesothelioma (https://www.cancer.gov/about-cancer/causes-prevention/risk/substances/asbestos/asbestos-fact-sheet#r12). This risk is thought to result from exposure to asbestos fibers brought into the home on the shoes, clothing, skin, and hair of workers. To decrease these exposures, Federal law regulates workplace practices to limit the possibility of asbestos being brought home in this way. Some employees may be required to shower and change their clothes before they leave work, store their street clothes in a separate area of the workplace, or wash their work clothes at home separately from other clothes (*https://www.cancer.gov/about-cancer/causes-prevention/risk/substances/asbestos/asbestos-fact-sheet#r2*).*

*Cases of mesothelioma have also been seen in individuals without occupational asbestos exposure who live close to asbestos mines ((https://www.cancer.gov/about-cancer/causes-prevention/risk/substances/asbestos/asbestos-fact-sheet#r12)).*

**Asbestos PCM Conversion**

The Air Quality sections of the DEIR include a newly introduced concept of converting asbestos measurements to PCM (phase contrast microscopy) units. There is no accepted method to convert between rock samples and air samples. The DEIR's approach of translating asbestos discovered in solid rock samples into PCM fiber concentrations in air is not possible. The PCM concept is from Appendix C: Asbestos Conversion Factors & Cancer Potency Factor, which is part of OEHHA's February 2015 Air Toxics Hot Spots Program Guidance Manual. OEHHA's conversion from fiber counts to mass as PCM fibers was developed exclusively for air samples. This is made clear in EPA's Airborne Asbestos Health Assessment Update document (USEPA, 1986. Airborne Asbestos Health Assessment Update. EPA/600/8-84/003F, Office of Health and Environmental Assessment, Washington, DC), which is referenced in OEHHA's Air Toxics Hot Spots Program Guidance Manual, Appendix C: Asbestos Conversion Factors & Cancer Potency Factor.

None of the DEIR's discussions regarding PCM conversions are valid. PCM cannot be used as a reporting metric, a compliance verification mechanism or a replacement for other methods of asbestos investigation. PCM asbestos conversion is not a concept that applies outside the world of asbestos air monitoring. During the DEIR comment period the NSAQMD contacted OEHHA with questions about the PCM conversion. OEHHA referred the NSAQMD to the California Air Resources Board (CARB) Risk Analysis Section, which worked with CARB's

Monitoring and Laboratory Division in providing an assessment of the underlying science. In short, CARB confirmed the non-validity of the applicant's PCM conversion approach. Following is an excerpt from a 3/28/22 email from CARB's Risk Analysis Section:

*I … wanted to clarify our earlier statement from our previous email regarding the risk calculations based on the lab reports, we initially attempted to convert TEMs into concentration in the air per the OEHHA guidance and ran it through HARP, but after discussing the outcome with others internally, it really isn't an appropriate way to calculate the risk (this was confirmed below with our MLD staff as well). Rather, you would need an annual average concentration from either sampled or modeled air concentrations, so our initial analysis no longer applies.*

*Staff from our Monitoring and Laboratory Division observed the following:*

***1. Determination of Risk from Rock Samples.*** *I agree with you, it is not appropriate to determine risk from rock samples. The asbestos fibers considered in Appendix C of the Hot Spots Guidance came from airborne samples during occupational exposure studies. I checked the 1986 U.S. EPA reference….*

*The PLM and TEM analyses in this DEIR were done on bulk samples (rocks), and the asbestos concentrations are reported in weight percent. It is not known how many asbestos fibers can be generated (and become airborne) from a given mass of asbestos-containing rock material. So there is no known conversion factor for the asbestos weight % (by TEM analysis of a rock sample) that can be used to estimate the number of PCM fibers/$m^3$ applicable for the Hot Spots risk assessment equation.*

***2. Calculation of asbestos weight % in TEM analysis report.*** *[This is in response to a separate question from the NSAQMD] The total asbestos weight % should be the sum of the chrysotile and amphibole asbestos weight percent. For sample **Y962990** (attached) it appears that there is an error in the report. Only 1 chrysotile fiber ≥5 µm is reported, and yet the weight % is 0.075. Comments describe actinolite fibers detected (an amphibole asbestos). Strange that a total weight % of <0.001 is reported.*

*For sample **Y962999** … I did not detect an anomaly in the TEM report. Chrysotile fibers can be much smaller and thinner than amphibole asbestos fibers. Many chrysotile fibers detected do not amount to much weight because they are so small or thin. CARB M435 PLM analysis of this sample is 2.5% asbestos by point-count. This is not unusual either. PLM analysis uses ~100,000 times more mass of sample than TEM analysis. It is best to start with PLM, and follow up with TEM for the PLM non-detects. TEM can miss out on finding the asbestos because the TEM sample mass is so low.*

***3. DEIR asbestos calculations (Appendix C).*** *For Appendix C (attached) there were no equations given on how TEM structures per nanogram and PCM asbestos weight percent were calculated in the first table that groups asbestos test results by rock type. In the next table, on the second and third pages (pages 56 and 57), there is a missing column for TEM weight % from the analyses.*

***4. Geological Units and Asbestos Testing (page 9).*** *The equations that [were] used for calculations of asbestos structures per nanogram and PCM asbestos by weight are not given. It is difficult to follow the discussion in this section because the lithology of the rock units is not described, and neither are the rock sample groupings clearly identified in Appendix C.*

NSAQMD recommends that the notion of PCM conversion should be thrown out because using OEHHA's air sampling PCM conversion formula for rock samples has the effect of making it look like there is less asbestos present than TEM laboratory work has demonstrated to be the case. Instead, the project's risk should be evaluated based on many more samples being gathered, and evaluated using TEM asbestos by weight. Those samples should be gathered in an approved, standardized manner (such as is set forth in Method 435) that employs composite collection practices rather than hand-picked pieces of core samples (which the tested samples were).

Using TEM to look at the same old core samples that were previously analyzed with PLM does have some value because we can now see how much asbestos the PLM method missed. PLM only detected asbestos in 2 of the 40 core samples, but the TEM method detected asbestos in 17 of the 40 samples, including in every rock type evaluated.

Both chrysotile and amphibole asbestos were discovered in the core samples. Chrysotile fibers tend to be smaller than amphibole fibers, making them more likely to become airborne and be transported great distances in the wind. Depending on weather conditions, they could be inhaled or deposited on surfaces in all parts of Nevada County for the 80-year duration of the project.

Note that the footnote on page 55 reads, "Samples containing naturally-occurring asbestos were from underground rock only; naturally-occurring asbestos is not known to outcrop at the surface of the Brunswick Site or Centennial Site." This is not the case – it could be that this was mistakenly left in the document from a version written before TEM was employed to get a closer look at the samples. While only 2 grab samples were taken from the surface of the 55-acre Centennial site, one of the two was found to contain 30-million chrysotile asbestos fibers per gram of rock, as is listed in the lab report for Sample Y962843 (ASUR Plan, unnumbered document page 106/131).

It is difficult to find the Health Risk Assessment among the many pages of the DEIR. It begins on unnumbered document page 356 of 1938 of Appendix E.1, as Appendix B of Appendix E.1. It should be noted that Appendix B of Appendix B of Appendix E.1, titled "Fugitive Dust TAC Concentrations" (starting on page 1,901 of the document) is missing asbestos. The Health Risk Assessment should be easier to locate.

The HARP report lists the maximum mitigated cancer risk as 3.34e-5 (group 543, p. 1839 of 1938) while the Appendix B, p. 1 reports the maximum cancer risk as 1.04e-5 (= 10.4e-6).

**Asbestos Sampling and Monitoring**

The NSAQMD has recommended that additional rock sampling be performed, and performed in a representative manner using composite samples, but it appears that no further sampling has been done (only further investigation of previously collected samples). There are still only 2 samples from the 56-acre Centennial site. All of the samples analyzed using TEM were previously analyzed using the inferior PLM method. The difference in the results from the two methods is large. PLM only detected asbestos in 2 of the 40 samples, but the TEM method detected asbestos in 17 of the 40 samples. This is mainly because PLM cannot detect small asbestos fibers, which are more easily entrained in the wind, can travel farther, and are inhaled deeper into the lungs.

It is unclear why the two serpentine samples originally evaluated using TEM were discarded from the 40-sample statistics and from consideration for the Health Risk Assessment. There were 42 samples analyzed using TEM, not 40. The two that were excluded are especially rich in asbestos. If all 42 samples are considered, the average asbestos concentration is 0.24% by weight.

In September 2020, the NSAQMD and Dudek communicated about monitoring. It would be ideal to have baseline monitoring data for at least a year before the project starts up. The NSAQMD suggested including a publicly accessible webcam (one for each site preferably) in the monitoring plan, as well as a MET site and a rain gauge. Monitoring specifics set forth in the Construction ATCM are available at CCR 93105(h)(3) and (h)(4). 40 CFR Part 58 (especially Appendix E) also contains relevant monitoring specifics.

**Asbestos Emissions**

Table 5 (App. E.1, document page 378/1938) lists construction emissions of .00003 tpy of asbestos, which is 0.06 lbs/year. This is incorrect. If we add the obvious dust from mitigated PM10 construction emissions due to off-road equipment (0.6 lbs/day) to the fugitive dust emissions (8.30 lbs/day) we get 8.9 lbs/day, or 3,248.5 lbs/year. TEM laboratory testing of 42 samples from the site yielded an average of 0.236355% asbestos content by weight. .236355 / 100 x 3,248.5 lbs/yr = 7.68 lbs/year, or 128 times the quantity of asbestos emissions presented in Table 5.

Dust emissions for the following 10 years are estimated at lbs/day from underground blasting (1.61) + ore processing (0.29) + fugitives (39.05) = 40.95 lbs/day, or 14,946.75 lbs/year. This comes to 35.33 lbs/year of asbestos emissions.

There is an Engineered Fill placement emissions table on unnumbered document page 303 that lists 37.95 lbs/day of PM emissions. The asbestos emission calculations are based not on the amount of asbestos present in the rock, but on the ASUR plan's goal of 0.01% asbestos in the engineered fill. The table at the top of the page includes emission factors. For the dumping of dump trucks, it includes emission factors for "material drop" from AP42, Table 13.2.4. The "material drop" emission factor is not for "material handling – blending." "Blending" implies disturbance that is continuous for some amount of time, whereas a material

drop is more or less instantaneous. The emission factor assumptions for the use of AP-42 section 13.2.4 should be explained. A material drop emission factor of 0.0001 lb/ton is used in the DEIR. However, the equation in 13.2.4 for material drop yields more than 6 times that amount if we apply a reasonable 5 mph wind speed and 3% moisture content.

**Emissions Estimate Assumptions**

On page 304, there are a few tables that are not explained. The rationale for using a silt content of 1.6% for the crushed rock and a moisture content of 15% for the sand tailings should be discussed. The normal ranges noted in AP-42 section 13.2.4 are a silt content of 0.44% to 19% and a moisture content of 0.25% to 4.8%. The choices taken in the DEIR for silt and moisture content result in lower emissions than the average anticipated values. Particularly since the waste rock has been crushed finely (beyond normal aggregate processing), the fill would have an increased concentration of fine particles/dust.

Additional assumptions on document page 304 that are questionable include a wind erosion area of 0.72 acres of active compaction, 0.34 acres access road and 1.00 acres either seeded or with covering underway. Elsewhere in the DEIR, it appears that more surface is to be disturbed that the area indicated in the assumptions on page 304. Likewise, the assumptions for bulldozing and compaction (2.43 hrs/day and 1.02 hrs/day respectively) seem to be less than indicated elsewhere in the DEIR.

The Logging and Chipping (described on page 4.3-56) is assumed to be for only 24 acres (Centennial and Brunswick sites combined). This is expected to take 11 years, so the assumptions divide 24 acres by 11 years to arrive at 2.18 acres per year, and it is assumed that logging and chipping will occur on only 1 day per year. It would be more realistic to consider that more than 2.18 acres might be cleared in a given year. Also, there is no mention of emissions associated with ongoing vegetation management.

Document page 306 contains logging & chipping emissions. There should be a source listed for the emission estimates. It is impossible to tell if the emissions are only from the equipment engines, engines plus tires, or engines, tires, root balls, fugitives from fans and loading limbs into the chipper, and so forth. Without an explanation there is no way to assess the validity of the numbers. From the tables on pages 307 and 308, it appears that those logging and chipping emissions listed on page 306 are only from the engines (which would be far less than if the entire process was evaluated). Following the chipping and logging estimates is a table that represents mobile sources associated with logging and chipping. However, it assumes that all operation is on paved roads and none of the vehicles are operating off-road, and only includes emissions directly from the vehicles (no fugitives). The emissions are based on EMFAC, which does not consider emissions from tires, fans and air displacement as vehicles navigate off-road to collect chips and logs.

The beginning of the Earthwork and Material Handling section (App. E-1, p. 24) reads, "Barren rock hoisted from the Brunswick shaft will be placed in the existing concrete silo located at the Brunswick Industrial Site. The barren rock will be transported from the concrete silo using a series of chutes and conveyors to a fully enclosed truck loading building. Barren rock may be

mixed with sands from the ore processing plant to create an engineered fill that meets appropriate geotechnical specifications for construction of development pads. Engineered fill would be transported from the ore processing facility to a receiving site, where it would be spread using a dozer."

Each transfer point along the "series of chutes and conveyors" is an emission point which is not accounted for in the DEIR.

Table 2 of the Health Risk Assessment lists the Base Elevation for the generators and diesel storage tanks in meters (placing them above 9,000'), whereas it should be feet.

The footnote for table 8 on page 28 of E.1 says, "Concentrate truck trip distance of 145 miles is based on the distance between the project sites and the Port of Oakland." There should be an explanation of why the 20 tpd of ore concentrate is going to the Port of Oakland. Is that where it is to be refined, or is it being shipped overseas for processing? If it is being transported overseas, the associated emissions should be included in the GHG analysis since GHG emissions are a global concern.

Unnumbered document page 184 of E.1 (for paved road fugitive emissions from vehicles) shows a table that makes no sense. It has fractions of vehicles making fractions of trips, and then rounds the VMT numbers that result before performing the final calculations. For instance, Freight Trucks have an average of 0.43 daily trips going 0.52 miles and lists their VMT as 0. It appears that the 0 miles travelled is the multiplied by the weight of the trucks, which would yield 0. It also shows only 1 concentrate truck trip per day, whereas elsewhere there are 10 concentrate trips/day. However, there are 5 concentrate truck trips listed on page 186 and 187. This is just an example. Not only concentrate trucks but also other vehicles show different mileage, different trips numbers, etc. throughout the emissions calculations throughout the document. These should all be corrected and standardized before the DEIR is considered adequate.

The emissions estimates assume that all on-site roads will be paved. This should be included as a condition or mitigation measure.

The spreading of 1,000 tons per day of engineered fill with a dozer should be considered in the off-road equipment emissions (dozers are considered to be off-road equipment).

Also, it is not clear how or where the rock is to be "mixed with sands from the ore processing plant to create an engineered fill that meets appropriate geotechnical specifications for construction of development pads." The off-road equipment list includes a "mobile auger blending plant," so it would be presumed that this is how the waste sand from the processing plant would be mixed with waste rock. Every time rock and dirt that contain asbestos are moved there is the potential for additional asbestos emissions. All of these emissions should be included in the Toxic Air Contaminant/Health Risk Assessment evaluation.

The last sentence under Earthwork and Material Handling reads, "Notably, for fill transported to off-site industrial sites (for year 2033 and beyond), emissions associated with fill placement were not included since it was assumed that the other industrial facilities are already receiving,

or would receive, fill from other sources." The big difference between fill transported from the proposed Mine to be deposited in unknown locations around the community contains asbestos. When considering airborne toxics it doesn't make sense to consider emissions from handling fill with asbestos in it as equivalent to emissions from handling fill without asbestos in it.

App. E-1, document page 380/1938 lists 3 diesel generators that would operate 8 hours per day, 7 days per week in perpetuity (operational). Yet, the emissions from these generators are not reflected in the various emission quantification efforts.

Table 4 (off-road construction emissions), p. 32 includes 9 portable diesel generators operating 6 hours/day, 6 days/week.

The Wastewater Septic System does not include any mention of how the wastewater is getting from the Brunswick mine area up the hill to the proposed septic field. The main buildings at the mine are at approximately 2740' and the upper portion of the septic field is at 2875'. Therefore, all of the sewage from the mine's 312 employees plus contractors, visitors and truck drivers has to be pumped a quarter mile up the hill across an elevation gain of 135'. If it is being pumped by a generator, those emissions should be quantified.

Emissions from construction of the septic leach field and quarter-mile sewage line running up hill to the septic system appear to be missing.

The OFFROAD model does not include fugitive emissions. It only includes engine emissions. The Operational Off-road Equipment list (App. E-1, document page 380/1938) lists plenty of off-road equipment at the Brunswick site. Table 8 (Off-Road Equipment Assumptions – Logging and Chipping) includes a grapple loader, a front-end loader, a skidder, a grinder and two excavators. PM/NOA emissions from those do not appear to be included in the TAC calculations, which specify that there would be zero emissions from off-road equipment. This doesn't seem possible given the amount of off-road disturbance from the variety of mobile off-road machinery, most of which moves dirt and rock as its primary function.

The "Earthwork and Material Handling Fugitive Dust" section starting on page 300 only includes a few of the construction activities that are anticipated (SF Creek Culvert Replacement, Pond Berm Repair, Service Shaft Collar and Building Pad). It assumes a serpentinite content (spelled "Sepentinite Concent" in the DEIR) in fill of 14.3%, with an asbestos content of 0.20%. A figure of 0.03% (which should be explained) appears to be derived from these numbers. Then there is a calculation of wind erosion that assumes a disturbed area of 4 acres. The resultant calculated fugitive dust emissions from wind erosion during construction is 0.41 tpy of PM10 and 0.02 tpy of PM2.5. The following unnumbered page (doc page 301) has an unlabeled table which seems to say that only 40,150 tons of fill would be placed per year (versus the proposed 365,000 tpy). The pages after that are unclear. For example, there is a sub-table called "Compaction" as part of the Fill Placement calculation series that notes a piece of equipment ("Cat563") that works for 0.06 hours per day. That is 216 seconds. On that same page is a bulldozer that moves 411.1 tons per hour and works 0.27 hours/day, which is 16 minutes and 12 seconds.

8

The reason for selecting 25 meters as the plume height and width for all of the line volume sources in Table 2 starting on page 8 of Appendix B of Appendix E.1 should be explained.

The DEIR cites AP-42, Ch. 13.3 as a source for blasting emissions information. ANFO is listed in that source as emitting 17 lb/ton of NOx. At 0.93 tpd of ANFO, that comes to 2.89 tons per year of NOx emissions from ANFO detonation. Nitrogen oxides are principally NO2, which is recognized as a TAC. These TAC emissions are not included in the DEIR. The "Underground Blasting and Crushing" section (p. 4.3-56) assumes no TAC emissions from blasting.

**ASUR Plan**

The NSAQMD is neither approving nor disapproving the ASUR Plan because there is no legal requirement for such a plan – it is part of the project planning documentation.

The ASUR Plan includes corrective actions for certain circumstances. The NSAQMD does not necessarily approve these actions in lieu of other actions or penalties that the NSAQMD or other agencies may prescribe or require. The ASUR Plan cannot be seen as being exclusively directive for the applicant or binding in any way on any agency, and should include a statement to that effect. The enforcement authority of agencies is unaffected by the ASUR Plan.

The ASUR Plan's shortcomings include difficulties with enforceability, uncertainty regarding the exact nature of control technologies to be used, the self-policing nature of the plan and a way to quickly evaluate its effectiveness.

The first page of the ASUR's Table includes the TEM % by weight, but the next two pages omit this statistic.

The summary table (1st page of Appendix C) is missing a sample. It appears to be sample Y962992, which has the highest concentration of asbestos of any of the rock samples (7.3 structures per nanogram, or 7,330,000,000 asbestos fibers per gram).

ASUR 5.0 paragraph 5 reads, "The great majority of mine tunneling in barren rock for the Idaho-Maryland Mine Project is expected to occur in the meta-andesite porphyrite "Brunswick Block". No asbestos was detected by PLM in samples from the meta-andesite porphyrite lithology. Asbestos was detected in six of the eighteen samples by TEM methods and the eighteen samples averaged 0.26 TEM structures per nanogram (s/ng) or 0.002% PCM asbestos by weight." Here again the conversion to PCM is unwarranted, since OEHHA's PCM conversion only applies to air monitoring samples. The TEM data sheets provide a calculated asbestos percentage, which averages to 0.192% asbestos by weight in the porphyrite samples. At this concentration, in the daily mining of 1,500 tons there would be 2.88 tons of asbestos. However, using the inferior PLM quantification technique there would appear to be no asbestos at all.

Similarly, Table 2 of the Vergence report illustrates the superiority of TEM to PLM analyses in the comparison of two results from the same core sample. The 1.1 foot-long core from hole #I-19-13, which was from a depth of 5090.50 feet to 5091.60 feet, was analyzed using both TEM

and PLM. The less reliable PLM method did not detect any asbestos but the TEM method detected 2.0% asbestos. The average asbestos content in the two TEM-evaluated samples of serpentinite was 2.8%.

The proposal to use PLM for compliance purposes may be convenient, but there is a big difference between PLM results and TEM results. TEM is preferred for asbestos quantification because it is able to detect smaller particles. A comparison between PLM and TEM results shows that there are a lot of asbestos fibers in the rock that are too small to be detected using PLM. Choosing to use PLM is, in effect, choosing not to see the asbestos.

Asbestos has been found in all of the kinds of rocks that were analyzed from the site (porphyrite, diabase, sand tailings, unmineralized serpentinite, weakly ankeritized diabase/serpentinite, ankeritized serpentinite, and serpentinite). With only a relatively few samples having been analyzed, there is no way to know how much asbestos is present in a given untested rock sample, but every fragment of rock or soil from the mine or the mine tailings could contain asbestos. When those rocks are broken or that soil is driven on or otherwise disturbed, asbestos fibers could be released to the air in unknown concentrations. Once airborne, tiny asbestos fibers can potentially travel many miles.

There is at least one serious mistake in the TEM lab reports. The sheet for sample Y962990 lists a "Calculated Asbestos Concentration (Weight %)" for chrysotile asbestos as .075% (29 million fibers per gram), so there is obviously an error in the reporting of the total as <0.001 %. The percentage of total asbestos can't be less than the percentage of a particular kind of asbestos.

Page 14, item 7 says that records of all analytical test work will be kept for a minimum of 7 years. Since asbestos related diseases often do not show up for 40 years or more, 7 years is not long enough for recordkeeping. Instead, the records should be kept (at least in electronic form) until at least 40 years after the mine closes.

Page 8, item 3 says, "Lithological units and gold mineralization will be adequately sampled and tested for naturally occurring asbestos…." The term "adequately sampled" is meaningless. Item 3 also includes some vague phrasing about testing using PLM and TEM. Is every sample to be tested both ways? How often? Also, in addition to converting TEM results to PCM with OEHHA's conversion formula, the TEM results should be reported and available to the public.

The ASUR Plan should include measures to prevent secondary asbestos emissions from workers' clothing and shoes. Historically, family members of individuals who have worked in mines where naturally occurring asbestos is present have been exposed to asbestos from the workers' clothing and shoes, resulting in asbestosis and mesothelioma. Asbestos exposures to the general public could also occur if workers carry asbestos-containing soil on their shoes and clothing into local places of business, such as restaurants, retail stores, fitness centers, etc. Showering on-site and changing shoes and changing and washing clothing at the end of a worker's shift is one way to prevent this type of secondary exposure. Alternatively, workers could wear protective suits and shoes that stay on-site. The manner of keeping asbestos from

leaving the site on workers' clothes, shoes and persons could be considered an airborne toxics mitigation measure.

The publication cited in the ASUR Plan, "NIOSH (2019). *Dust control handbook for industrial minerals mining and processing. Second edition*. https://doi.org/10.26616/NIOSHPUB2019124" discusses additional options for dust control, including the use of wind fences, fixed water spray systems and crust-forming agents, and covering inactive areas with clean gravel. The discussion of dome enclosures on page 357 of that document in particular should be reviewed (large ones can span a thousand feet and they can withstand 90-mph winds and heavy ice loads). Such technologies should be discussed/evaluated in the DEIR

As the tunnels progress and more samples are tested for asbestos, an ever-increasing knowledge base will develop. There should be a way to refine the ASUR Plan and reassess the project periodically. As a precedent, Teichert Aggregates has a 5-year conditional use permit review requirement for their Martis Valley operation near Truckee. If it is found that asbestos emissions are great enough to create a significant health risk, there should be a way to put the project on hold for as long as necessary to find ways to bring the asbestos emissions down, such as through additional or new technologies. It would be short-sighted to commit to the ASUR Plan for the entire life of the mine based on the few samples that have been tested so far. As time passes, technology advances. There may be a way to quickly monitor for asbestos emissions or assess the asbestos content of the rock body in the future. Control technology also advances, and someday there may be ways to further reduce the release of microscopic airborne asbestos fibers into the community.

Some of the gold veins are known to be hosted entirely in serpentinite. The NSAQMD recommends considering leaving those veins untouched for at least 40 years, by which time emission control technology is likely to have improved. Electrostatic mist screens, for example, show promise among emerging technologies.

**Water**

The Water Supply Assessment (WSA) is important because an abundant supply of water is necessary for the control of dust and toxics such as silica and asbestos. Unfortunately, it does not include enough detail to evaluate its accuracy. There should be an itemized list, or inventory, of water usage features so that reviewers can check to see if key elements are being overlooked or mischaracterized.

The water usage estimates are based on usage at "buildout." The document considers the first 10 years as the "construction" period because that is when the waste material is being deposited and compacted as engineered fill at the Centennial and Brunswick sites. It reads, "Because this WSA is assessing the impacts at buildout of the Proposed Project, the water demand during construction will not be included in buildout water demands." However, the buildout phase is not when the project would use the most water. That is, unless the eventual off-site compaction of engineered fill were to be included in water usage, that would increase the buildout consumption, especially since it would require an abundance of water due to the

11

presence of asbestos in the fill and the resulting requirement to comply with the Asbestos Airborne Toxic Control Measures for all fill placement activities (not discussed in the DEIR).

The DEIR estimates 5,700 gpd of potable water for sinks, toilets, showers and laundry. It would be important to have adequate shower capacity at the facility for the hundreds of anticipated employees. Workers in the mine would continually be subject to air saturated with moisture to the point of it dripping off their clothing (the DEIR specifies that there would be 100% saturation of the air in the mine). Dust laden with asbestos and other toxic substances would stick to skin, hair and clothing. Workers should not be allowed to leave the site with asbestos dust on their bodies, clothes or shoes because they would carry the asbestos dust into public places or home to people they live with.

A key question regarding water use assumptions is if the non-potable water would be of high enough quality to use for "100 percent saturation of air" (estimated at 40,000 gpd). If it has elevated levels of natural contaminants (such as arsenic, mercury and other heavy metals, iron and manganese) or if it has too much of the proposed water treatment and ore processing chemicals, it may not be suitable for employees to breathe. Water pumped from the mine would contain numerous substances including sodium hypochlorite (bleach), ammonia (partly from detonation of 1,860 lbs/day of ANFO explosive), potassium permanganate, sulfuric acid, sodium hydroxide, sodium bisulfite, assorted lubricants and petroleum products lost from equipment, and reagents including Aerofloat 208 (odor of alcohol and sulfur), Aerophine 3418A, Aerofroth 70-MIBC (odor of alcohol), Magnfloc 10 and Scaletrol PDC9401.

The ASUR Plan proposes that unpaved areas will be watered for dust suppression every 2 hours, which should be considered carefully in the WSA. The NSAQMD is concerned that the water budgeted for the project might not be adequate to meet the dust control requirements. Since the dust contains asbestos, silica and numerous other toxic substances, adequate dust control is necessary. There should never be a situation where dust control is compromised because of water usage restrictions, particularly in the summer months when the potential for dust generation is greatest.

https://www.epa.gov/sites/default/files/2019-04/documents/mr_guidanceforapplicationfordustcontrolpermit.pdf contains some "rules of thumb" for estimating water usage. For example, grading uses approximately 10,000 gal/acre per day; 30 gallons is required for each cubic yard moved; and pre-wetting areas to be disturbed requires 1 acre-foot of water (325,851 gal) per acre of land. The Health Risk Assessment (page 3) says that 104 acres are to be disturbed.

A lot of water is also needed for grinding mills, crushers, conveyors, conveyor transfer points and drop points to control emissions of dust and asbestos.

## AGENCY LETTER 12: SAM LONGMIRE, NORTHERN SIERRA AIR QUALITY MANAGEMENT DISTRICT

### Response to Comment Agcy 12-1

This letter is superseded and replaced by Agency Letter 11. Please see comments made in Agency Letter 11 and Response to Comments Agcy 11-1 through Agcy 11-20 above.

March 23, 2022

Mr. Kelley:

The Alliance for Workforce Development, Inc. (AFWD) is Nevada County's local workforce development organization. We are dedicated to enhancing the quality of life throughout the communities we serve.

**Grp 1-1** Our mission is to empower people to find job training and new opportunities to build or expand a career for themselves. Every day we work to help people who are trying to find a new path forward economically, sometimes under very difficult circumstances. We sit on the front lines of the current economic crisis. The effect of COIVD-19 in particular has caused tremendous disruption and displacement for many in the communities we serve.

**Grp 1-2** We met with Rise Grass Valley CEO Ben Mossman to discuss recruiting and job training opportunities available through AFWD. Rise Grass Valley has signaled to us a willingness to recruit a diversified workforce, to conduct extensive on-site job training, and to work with our local schools and colleges to develop essential training programs for potential hires.

In addition to the direct jobs, Rise Grass Valley anticipates that roughly 300 indirect new jobs could be created by the economic multiplier that the mine will demand – anything from related construction work to demand for more restaurants and hotels. This can be a tremendous lift to our entire local economy and workforce.

**Grp 1-3** We are very encouraged that Rise Grass Valley reached out to us to discuss a meaningful collaboration. We count on employers like them to proactively consider their future workforce needs, and to treat their growth in the community as a mutually beneficial partnership. Should the project move forward, we are committed to working with Rise Grass Valley for all their workforce needs.

If you have any questions, please feel free to contact me.

Sincerely,

Kristine ZuaZua

**RE: Idaho-Maryland Mine Project Draft Environmental Impact Report, SCH# 2020070378**

Dear Mr. Kelley,

On behalf of the Board of Directors, staff, and over 700 members of the Bear Yuba Land Trust (BYLT), I am submitting the following comment letter regarding the Draft Environmental Impact Report (DEIR) for the proposed Idaho-Maryland Mine (IMM) project (Project). BYLT also submitted a comment letter on the Notice of Preparation (NOP) that was dated August 17, 2020. We are disappointed to find that many of our comments were not specifically addressed in the DEIR at a level of detail commensurate with the environmental impacts of the proposed Project.

Grp 2-1

**Who We Are**

The mission of BYLT is to protect and defend the working and natural lands of the Bear and Yuba River Watersheds. The lands under our care include conservation easements covering over 18,000 acres of forests, ownership of land leased to Mountain Bounty Farm and a working cattle ranch on the Bear River, and the maintenance and construction of more than 45 miles of publicly accessible trails in Nevada and Yuba Counties. We believe that long-term planning, with a goal of sustainability and resilience in the face of many unknown climate change and development impacts, must be at the forefront of all decision-making. BYLT is accredited by the Land Trust Alliance (LTA) and is recognized as a land conservation organization that meets national standards for excellence, upholds the public trust, and ensures that conservation efforts are permanent.

PO Box 1004, Grass Valley, CA 95945 • *phone:* (530) 272-5994 • *fax:* (530) 272-5997 •
www.BearYubaLandTrust.org

**Bennett Street Grasslands Conservation Easement**

Impacts posed by the IMM Project to our 7-acre Bennett Street Grasslands Conservation Easement (Easement) located along East Bennett Street just below the Brunswick site and south of the Centennial site are of great concern (see Attachment 1, Map). This valuable natural asset, owned by California State Parks and protected by BYLT, is bisected by South Wolf Creek, into which the Project will be releasing at least 5.6 cubic feet per second (cfs) of potentially polluted residual mine water.

BYLT is legally bound to protect the conservation values of the Easement property from outside impacts in perpetuity. As stated in the Deed of Conservation Easement dated November 30th, 1999 (see Attachment 2, Conservation Easement), the natural, ecological, and aesthetic values of the Property (which includes South Wolf Creek) are to be preserved and maintained by the continuance of protection in perpetuity, and "to enhance the restoration of the ecosystem, the natural systems and processes, and the aesthetic values of the Property".

**Grp 2-2**

The rights conveyed by the Easement include "the right to identify, to preserve and protect in perpetuity, and to enhance the natural and open space, the ecological, scenic and aesthetic features, the water resources, and the natural flora and fauna on the Property." BYLT is required to monitor the Easement yearly and provide a report to State Parks. We are also required to implement a Management Plan prepared for the Easement. The report and Management Plan note that riparian thickets along the creek and associated grasslands provide important habitat including nesting and foraging opportunities for many bird species, including rare and endangered birds. Ecologists have noted that the grassland is one of the best examples of what Grass Valley looked like prior to European settlement. As a result, monitoring activities have been completed on the Easement by the local chapter of the Audubon Society, California State Parks, and other local bird groups such as Gold Country Avian Studies, which has conducted bird banding at the site for over 5 years. California State Parks has been managing various invasive species and conducting in-stream restoration in the creek to preserve the habitat values of this protected riparian corridor (Attachment 3, Photos).

**Impacts to Legal Obligations of Bennett Street Conservation Easement**

The proposed Project has the potential to significantly affect our ability to meet our legal obligations, i.e., to protect and defend ecological habitats contained within our conservation easements, yet this is not described anywhere in the DEIR. We are very concerned that the Project will adversely affect water quality and quantity in South Wolf Creek and the conservation values of this valuable Easement beyond what is described in the DEIR. As stated in the Deed, "the Property consists of six general ecosystems within the Northwest Sierra Nevada Ecological Subregion of California, with a large population of rare California Reedgrass Tall Closed Graminoid community, a madrone forest of unusual stature, and a montane riparian forest community which provides nesting, foraging, and cover for a variety of common wildlife species, including California black bear, and mountain lion". Yet, direct impacts to these sensitive habitats as a result of sending an additional 5.6 cubic feet per second (cfs) of

**Grp 2-3**

2

potentially contaminated wastewater through the Easement are not addressed in the DEIR. This is a violation of CEQA.

According to CEQA Section 15125(a), "An EIR must include a description of the physical environmental conditions in the vicinity of the Project. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant." The obvious purpose of this requirement is "to give the public and decision makers the most accurate and understandable picture practically possible of the Project's likely near-term and long-term impacts." The Less than Significant impact finding for natural communities and special-status species is based on a study area that is far too narrow to make this conclusion.

As a land trust, BYLT has been entrusted by the community, its members, landowners, and local jurisdictions to protect and preserve our Easements. This is done using vital financial, administrative, and legal resources. To diminish our ability to provide these services and accomplish our mission reduces our ability to defend conservation values and broker new agreements with willing landowners. If we cannot guarantee protection, our mission is compromised. Yet, this is not discussed in the DEIR Land Use Section 4.9-2 (page 4.9-18) under consistency with plans and policies as required by CEQA.

This section of the DEIR should not just discuss County policies, but also the policies of partner organizations such as BYLT. In fact, Nevada County General Plan policies directly relate to BYLT, yet are not discussed or described. Excerpts from the General Plan include the following:

**Objective 11.5: Support the acquisition, development, maintenance and restoration, where clearly consistent with General Plan policies, of habitat lands for wildlife enhancement.**

**Directive Policies Policy 11.10: Cooperate with State and Federal agencies and public and quasi-public organizations and agencies in the acquisition, restoration, and maintenance of habitat lands.**

**Policy 6.10: The County shall support the activities of the Nevada County Land Trust [now BYLT] and Truckee-Donner Land Trust to acquire and manage open space lands. These non-profit Trusts shall be encouraged to acquire open space through dedication or voluntary purchase from willing sellers of property of easements. The Trusts shall be encouraged to acquire land or other real property interests which could focus on lands which contain unique, valuable or sensitive resources reflecting environmental or biological sensitivity; scenic landscape units; community separators; historic, cultural, and archaeological content; and low intensity recreational potential.**

These General Plan policies are not discussed in any section of the DEIR and the project's inconsistencies with these important policies is not identified. This is a violation of Section 15125 of the CEQA Guidelines and we ask that the section be revised and the DEIR recirculated with this information. The long-term viability of land trust property rights must be disclosed and defended so that we can best protect the conservation purposes of the Easement.

3

**Habitat and Ecological Value of Bennett Street Conservation Easement**

The Bennett Street Conservation Easement Property is documented habitat for the State-listed as Endangered willow flycatcher (*Empidonax traillii)* and three California Department of Fish and Wildlife (CDFW)-listed Species of Special Concern: olive-sided flycatcher (*Contopus cooperi*), yellow-breasted chat (*Icteria virens)*, and yellow warbler (*Setophaga petechia*). These birds have been documented within the grasslands and riparian corridor of the Property. In addition, the South Fork of Wolf Creek flowing through the Property possesses habitat for the following federal and California Department of Fish and Wildlife species of concern which have been reported in the nearby surrounding area: Foothill yellow-legged frog, ( *Rana boylii*) and Northwestern Pond Turtle, (*Clemmys marmorata marmorata*). Many other non-listed species depend on the South Fork of Wolf Creek for habitat, and food sources found in this declining habitat in the Grass Valley area of Nevada County, California.

The Conservation Easement states, "WHEREAS, all of these natural, ecological, and aesthetic values are of great importance to the Grantor and to the people of the State of California, and are worthy of preservation; and WHEREAS Grantor desires and intends that the natural, ecological, and aesthetic values of the Property be preserved and maintained by the continuation of patterns of land use on the Property that will not interfere with or substantially disrupt the ecosystem or workings of the natural systems."

**Grp 2-4**

Again, we find no meaningful discussion of the ecological value of the Easement or a discussion of how the Project will affect the water quality and quantity that would flow through South Fork Wolf Creek post-Project affecting animal and plant communities in the Easement. The preparers of the DEIR seem to believe that the Easement is currently disturbed similar to the Centennial and Brunswick Industrial Sites. Nothing could be further from the truth. The condition of South Wolf Creek on the Easement has been protected for at least 24 years by BYLT. It is a natural and protected channel in this location, yet that is not recognized in the DEIR. This condition and the potential impacts of the Project must be analyzed in this context as required by CEQA and feasible mitigation measures, including rigorous pre-construction surveys and post-construction mitigation monitoring for these specific and other communities must be evaluated. In addition, the ecological values of the seasonal and perennial wetlands on the Easement must be evaluated for impacts.

For example, there is no specific discussion of the effects on benthic macroinvertebrates and amphibians within South Wolf Creek. This includes the federal- and state-listed foothill yellow-legged frog which may be most impacted by increased flows as tadpole eggs and invertebrates may get washed downstream and are unable to complete their life cycles. As benthic macroinvertebrate numbers decrease in the channel, fish, such as brown trout present in the creek, may also decline in numbers as their food source declines. To say that the proposed Project would not result in temporary or permanent impacts because encroachment would not occur within 100 feet of the waterway does not account for direct impacts just downstream to water quality, quality, and wildlife.

4

**Impacts to Riparian Corridor**

Increased flows in South Fork Wolf Creek may change the plant community composition and distribution along areas adjacent to the creek. Conditions may be too wet for some plant species to grow and they may be displaced from the site all together. This situation would not only affect plant species, but also the inter-related habitats for aquatic and nesting and foraging bird species that utilize the Easement. We can find no discussion of these CEQA impacts in the DEIR.

**Grp 2-5**

As currently proposed, the Project will alter the hydrology and hydroperiod of South Fork Wolf Creek. The current base flow of South Fork Wolf Creek is approximately 2 cfs. Under the proposed Project, flows would increase to over 7 cfs for 80 years during Project operations. The distribution of seasonal and perennial wetlands located within the Bennett Street Grasslands Easement would change over time in response to the changes in hydrology of the creek. How will this impact be monitored in the long-term? We can find no discussion of these CEQA impacts in the DEIR. Further, we can find no visual representations such as cross-sections of the creek to show how much water an additional 5.6 cfs will raise water levels. This is vital information for the decision makers and public to have when considering potential impacts.

**Wildlife Migration/Movement Corridors**

**Grp 2-6**

The discussion in the DEIR related to wildlife migration/movement corridors is limited to deer on the Brunswick and Centennial Industrial Sites This is inadequate. The corridor of the South Fork Wolf Creek and the entire Easement site are vital wildlife movement corridors that could be affected by changes to water quantity and quality. Evidence of numerous large mammal and raptor species is easily seen on the Easement property. The inter-related nature of ecological communities is not acknowledged in the DEIR. When one species is adversely affected either by poor water quality and a change in food sources, other species are affected as well. This impact, which is a specific question in Appendix G of the CEQA guidelines, has not been adequately answered. This is a violation of CEQA.

**Insufficient Surface Water Quality Monitoring and Sampling**

**Grp 2-7**

No baseline surface water quality data is included in the DEIR and therefore, the background concentrations of basic water quality parameters such as inorganic cations and ions, metals, total suspended solids, pH, dissolved oxygen (DO), and water temperature in South Fork Wolf Creek are currently unknown. When the mine begins operations and begins pumping water into the creek to dewater the mine shafts, the change in water chemistry will be unknown because there is no baseline data to compare to the Project conditions.

As previously stated, CEQA Section 15125(a) states that "An EIR must include a description of the physical environmental conditions in the vicinity of the Project." We cannot find any mention of baseline monitoring of surface water quality of South Fork Wolf Creek, especially considering concerns related to changes to pH, temperature, DO, and turbidity. Impacts to

5

water quality in the DEIR are founded on the assumption that compliance with NPDES-permit-regulated-discharge requirements will protect aquatic biological resources. This assumption is not adequate for this Project, especially when a baseline of existing conditions has not been provided, is a violation of CEQA.

We propose that baseline surface water sampling in South Fork Wolf Creek should be completed monthly to obtain surface water quality data that represents pre-Project conditions. In addition to monthly sampling, the following should be completed:

- Sampling during or just following the "first flush" storm event of the season (greater than 2 inches rain in Grass Valley); and
- Sampling during or just following qualifying rain events (greater than one inch of rain in Grass Valley).
- Both filtered and unfiltered samples should be obtained during each sampling event and analyzed for constituents of concern in addition to other metals and inorganic constituents. Once a statistically significant number of surface water samples is obtained, baseline data for each constituent of concern can be established. If and when discharge of treated mine water commences, sampling should continue at least quarterly and during storm events as described above. Data would be compared to the established background levels to determine whether water quality exceeds site specific water quality goals. There is no mention of post-Project surface water quality sampling. This testing is only meaningful with a statistically significant database of background surface water quality constituents.

**Regional Water Quality Control Board Requirements**

We find the following statement to be grossly insufficient with surface water compliance standards. The Project Description (DEIR page 3-15) states:

"Water produced during dewatering would be treated prior to discharge to South Fork Wolf Creek. It is anticipated that the discharge would occur in compliance with the Central Valley Regional Water Quality Control Board Order No. R5-2016-0076, National Pollutant Discharge Elimination System (NPDES) No. CAG995002, which was adopted on October 14, 2016."

**Grp 2-8**

The samples used to determine constituents of concern for water treatment came from the Brunswick Shaft. The drains off of Idaho Maryland Road would have been a more appropriate sample location to assess water quality of the pumped groundwater. A project of this magnitude should know and disclose at this stage exactly what Regional Board orders and permits to which it must comply. To not include actual regulatory requirements of what measures are required to meet Regional Board requirements pertaining to the discharge of potentially hazardous wastewater, does not give the public or decision makers a realistic understanding of the impacts of the proposed Project. What mitigation measures will the Regional Board require? To relegate the identification of mitigation measures to a future time is the definition of deferring mitigation, which is not allowed under CEQA.

6

There are no specific Regional Board requirements provided in the Project Description section of the DEIR. Therefore, we cannot be certain that "The water discharged into South Fork Wolf Creek is expected to be at least as good or better quality than the water typically flowing through South Fork Wolf Creek." (DEIR page 3-18). The document implies that because the Project has not yet been developed to a level of detail needed to include these important specific mitigation measures, they do not need to be included. CEQA requires that the project description supply the amount of information needed for evaluation and review of the environmental impacts (Section 15124 of the CEQA Guidelines). In addition, all mitigation must be identified and feasible. Mitigation measures are required to read as "shalls" rather than "woulds" and those included "as part of the Project", must so state.

We find that there is substantial evidence showing the creek's water quality would be adversely affected by Project-generated surface water runoff. Total maximum daily load (TMDL) was not used to measure this project impact; therefore, we find that the DEIR failed to determine its significance, either individually or cumulatively.

**Grp 2-9**

In addition, we are very concerned about turbidity and water quality impacts during construction of the water treatment facility and other grading at the Brunswick Industrial Site directly upstream from the South Fork Wolf Creek. While a Stormwater Pollution Prevention Plan (SWPPP) will be required, in our experience, these are generally inadequately monitored. Contractors often self-monitor and their BMPs are commonly installed inadequately. A third-party firm should be in charge of preparing and monitoring the SWPPP and all conditions and penalties for violations must be described in the DEIR. Otherwise, the mitigation is not identified and CEQA is violated because the mitigation is not included in the Project. CEQA does not allow the deferral of mitigation to the future.

**Martis Valley Case Law Precedence**

**Grp 2-10**

In the sections above, we have factually stated many areas in which the proposed project would result in potentially significant impacts to the Bennett Street Grasslands Conservation Easement. Yet, these impacts are not disclosed or discussed in the DEIR. A recent, local court case *(League to Save Lake Tahoe, Mountain Area Preservation, et al./California Clean Energy Committee v. County of Placer, et al. (Sierra Pacific Industries, et al., Real Parties in Interest) (2022)* Cal.App.5th., also known as the Martis Valley Case) sets important legal precedence for evaluating established CEQA rules and principles, including, but not limited to, those governing: applicable standards of review; baseline/environmental setting description; lead agency discretion regarding thresholds of significance, methodology for impact study, and significance determinations; cumulative impacts (including GHG) analysis; and requirements for adequate mitigation measures.

Similar to the conclusions of the Martis Valley Case, we find that the DEIR fails to provide baseline/environmental setting description; provides poor methodology for impact study, and significance determinations; cumulative impacts analysis; and adequate mitigation measures.

7

**Alternatives**

Section 6.4 of the DEIR attempts to describe an Environmentally Superior Alternative as required by Section 15126(e)(2) of the CEQA Guidelines. The section states that Alternative 2 is the Environmentally Superior Alternative, yet we believe a combination of Alternatives 2 and 4 is more appropriate and would meet the main objectives of the project while substantially reducing environmental impacts. This combination, which is feasible and reasonable (as defined by CEQA), would include no placing of mine tailings at the Centennial Site, yet would still include clean-up as required by DTSC. Further, reducing the extraction as described in Alternative 4 without extending the number of years the mine is in operation would further reduce impacts while also eliminating the need for fill to be deposited on the Centennial Site. This environmentally superior alternative would also reduce the potential for adverse water quality and quantity impacts to South Fork Wolf Creek, as described earlier in this letter. Please revise the DEIR to include this more Environmentally Superior Alternative.

**Grp 2-11**

**Statement of Overriding Considerations**

CEQA Guidelines Section 15093 states the following:

"CEQA requires the decision-making agency to balance, as applicable, the economic, legal, social, technological, or other benefits, including region-wide or statewide environmental benefits, of a proposed project against its unavoidable environmental risks when determining whether to approve the project. If the specific economic, legal, social, technological, or other benefits, including region-wide or statewide environmental benefits, of a proposal project outweigh the unavoidable adverse environmental effects, the adverse environmental effects may be considered "acceptable." The agency must state in writing the specific reasons to support its action to approve based on the Final EIR, supported by substantial evidence in the record.

**Grp 2-12**

We encourage the County Board of Supervisors to carefully consider how the economic benefit to mine operators and owners outweighs the significant environmental impacts of the proposed Project. The Board of Supervisors has the ability, in fact, it is their obligation, to deny the project based on its lack of benefit to the community.

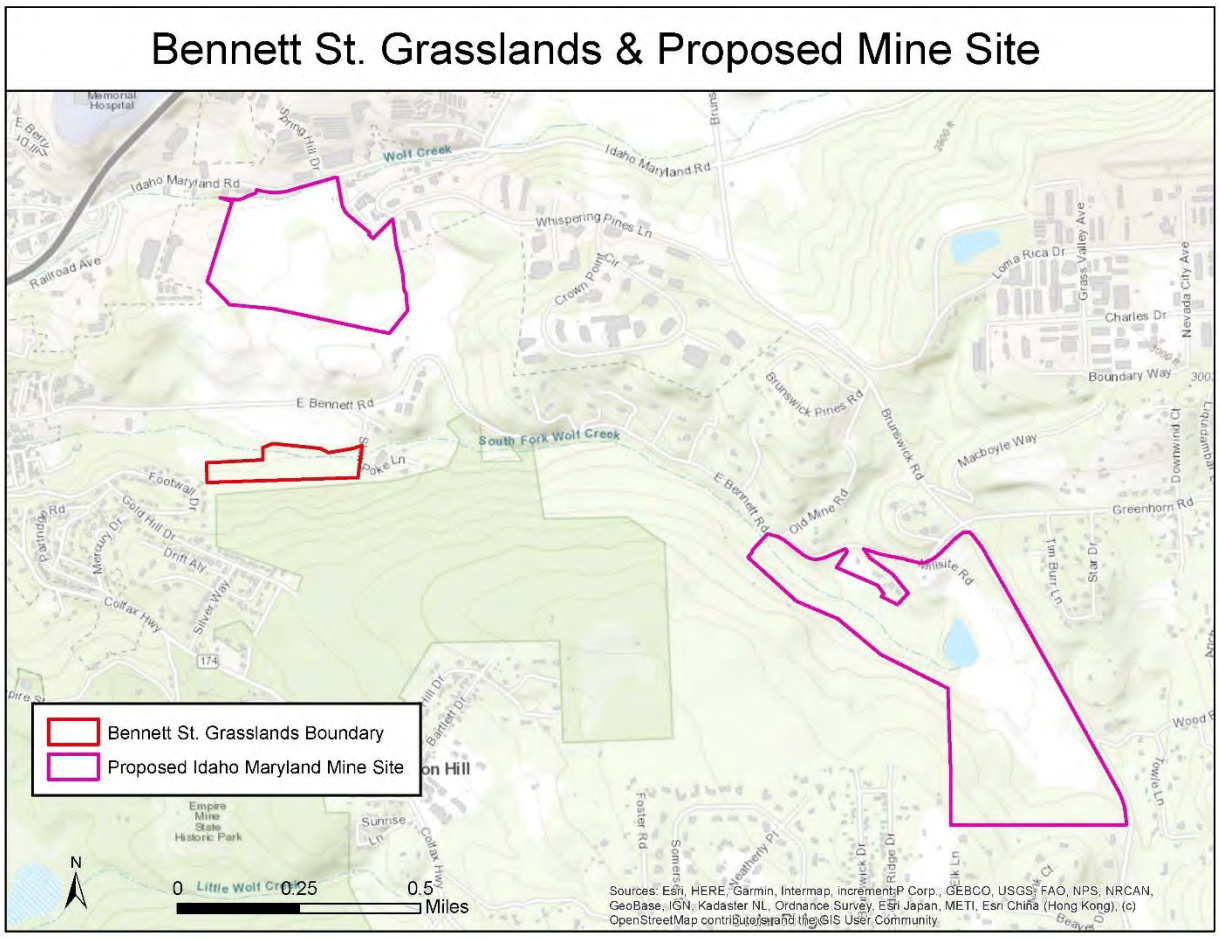
**Conclusion**

We have identified many inadequacies of the DEIR in this letter. For these reasons, we believe the DEIR must be corrected and re-circulated for public comment. The CEQA process for this Project must give the decision makers and the public every opportunity to understand the potential impacts of the Project as well as to identify feasible, comprehensive, and specific mitigation measures. Otherwise, the public can have no certainty that far-reaching adverse impacts will not occur.

**Grp 2-13**

8

For over 30 years, BYLT has safeguarded critical habitats and provided assurances to our community that we will protect the conservation values of the lands we are entrusted with. We are legally bound to protect the Conservation Easement values of the Bennett Street Grassland Conservation Easement and the Project puts our ability to accomplish our mission in legal jeopardy. For all of the above reasons, we find the Draft EIR to be legally insufficient to support the Idaho-Maryland Mine Project.



Respectfully Submitted,

Erin Tarr
Executive Director
Bear Yuba Land Trust
erin@bylt.org

DEED OF CONSERVATION EASEMENT

THIS GRANT DEED OF CONSERVATION EASEMENT (this "Easement"), made as of this November 30th, 1999, by Robert T. Roark, Trustee udt dated 4/13/84 whose address is Box 670, Grass Valley, California, 95945 and John P. O'Brien and Claire E. O'Brien husband and wife; and John P. O'Brien and Claire E. O'Brien as trustees of the John and Claire O'Brien Trust dated 3/30/95 whose address is 17072 Norlene Way, Grass Valley, California, 95949 (hereinafter referred to as the "Grantor"), and NEVADA COUNTY LAND TRUST, a California non-profit corporation whose address is P.O. Box 2088, Nevada City, California, 95959 (hereinafter referred to as the "Grantee"); (collectively, the "Parties");

WITNESSETH:

WHEREAS, Grantor is the owner of the following real property in Nevada County, California located at Bennett Street east of Grass Valley city limits more specifically described as a portion (portions) of Nevada County Assessor parcel numbers 09-560-06 and 09-560-23 (hereinafter referred to as the "Property"), described in Exhibit A attached hereto and made a part hereof; and

WHEREAS, the Property constitutes a valuable element of the foothill cottonwood-willow riparian forest and California native grassland habitat, and its ecological, scenic, and aesthetic and open space values as recognized in California acts and statutes; and

WHEREAS, the Property consists of six general ecosystems within the Northwest Sierra Nevada Ecological Subregion of California, with a large population of rare California Reedgrass Tall Closed Graminoid Community, a madrone forest of unusual stature, and montane riparian forest community which provides nesting, forage and cover for a variety of common wildlife and species, including California black bear, and mountain lion; and

WHEREAS, the Property does possess the habitat for the following federal and California Department of Fish and Game species of concern which have been reported in the nearby surrounding area: Foothill Yellow-legged Frog, *Rana boylii*, Northwestern Pond Turtle, *Clemmys marmorata marmorata*; and

-1-

~~U42858~~

013132

WHEREAS, maintenance of such habitat helps support many other non-listed species dependent on the water source, nesting habitat and food sources found on this declining habitat in the Grass Valley area of Nevada County, California; and

WHEREAS, all of these natural, ecological, and aesthetic values are of great importance to the Grantor and to the people of the State of California, and are worthy of preservation; and

WHEREAS, Grantor desires and intends that the natural, ecological, and aesthetic values of the Property be preserved and maintained by the continuation of patterns of land use on the Property that will not interfere with or substantially disrupt the ecosystem or the workings of the natural systems; and

WHEREAS, Grantor, as the owner in fee of the Property, owns the rights to identify, to preserve and protect in perpetuity, and to enhance the restoration of the ecosystem, the natural systems and processes, and the aesthetic values of the Property; and

WHEREAS, Grantor desires and intends to transfer certain of such rights to the Grantee for the express purpose of furtherance of the identification, preservation and protection in perpetuity and the enhancement and restoration of the ecosystem, the natural systems and processes, and the aesthetic values of the Property; and

WHEREAS, Grantee is organized to preserve and conserve natural areas and significant land for ecological, scenic, aesthetic, charitable, recreational and educational purposes; and

WHEREAS, the State of California has recognized the importance of private efforts toward the preservation of natural systems in accordance with the laws of California; and

WHEREAS, the Grantee is a qualified private organization under the terms of California State Code and is qualified to receive and hold conservation easements as provided in California Civil Code Sections 815 and 816; and

WHEREAS; the Grantee is an organization described in Section 170 (h)(3) of the United States Internal Revenue Code qualified to receive and hold conservation easements;

NOW, THEREFORE, in consideration of the mutual covenants contained herein, and pursuant to state code, Grantor hereby conveys to Grantee this Easement, for the express purposes as set forth herein, consisting of rights hereinafter enumerated, on, over, and across the Property.

~~042858~~ 013132

SECTION I - RIGHTS CONVEYED

The rights conveyed by this easement are the following:

A. Identification and Protection. The right to identify, to preserve and protect in perpetuity, and to enhance the natural and open space, the ecological, scenic and aesthetic features, the water resources, and the natural flora and fauna on the Property, in the manner set forth in this Easement; subject, however, to Grantor's reserved rights as described in this Easement.

B. Access. The right to enter upon the Property to inspect the same and enforce the rights herein granted, and to observe, study, and make scientific observations of its ecosystems, at such times and frequency as is reasonable for the furtherance of the express conservation purposes of this Easement and in a manner that will not unreasonably interfere with the use of the Property by Grantor, or with the rights of the others on the Property, if any. Notwithstanding the foregoing, in addition, Grantee shall have the right of immediate entry upon the Property if, in Grantee's sole judgment, such entry is needed to prevent damage to or the destruction of the conservation purposes of this Easement.

C. Injunction and Restoration. The right to enjoin any activity on, or use of, the Property which is inconsistent with this Easement, and to enforce the reasonable restoration of such areas or features of the Property as may be damaged by such activities and consistent with the management plan by the Nevada County Land Trust, the Nevada County Conservation Alliance and The Empire Mine State Historic Park, California Department of Parks and Recreation (the "Management Plan") .

SECTION II - GENERAL EFFECT OF EASEMENT

A. Perpetual Restrictions. This Easement shall run with and burden the title to the Property in perpetuity and shall bind Grantor and all future owners and tenants of the Property.

B. Permitted Uses in General. This Easement is in gross, shall confine the use of the Property to activities such as are consistent with the express conservation purposes of this Easement, the terms of this Easement, and ecological study.

C. Dedication of Premises. Pursuant to the terms of applicable state code, the Property preserved by this Easement is declared to be open and natural land, and may not be converted or directed to any uses other than those provided for in this Easement.

~~042858~~ 013132

SECTION III - PERMITTED USES AND PRACTICES

The following uses and practices, are not inclusive of all permitted uses and practices, are illustrative of permitted uses and practices that are presently or may hereafter be recognized by and acceptable to the Grantee as being consistent with and in furtherance of the express purposes of this Easement, and, as such, these and other consistent uses and practices may not be precluded, prevented, or limited by this Easement.

A. Boardwalk. Installation of a boardwalk to minimize impacts of study and educational activities after consideration of the environmental impacts of such a boardwalk, and whose construction shall be minimally intrusive and consistent with the management plan.

B. Hazardous Tree Removal. Removal of hazardous trees or portions thereof, if as determined by Grantee, if there is imminent danger to life or property.

C. Implementation of Management Plan. Implementation of recommendations in the management plan to restore and/or maintain the health of native grasslands and riparian and aquatic habitats that ensure long-term sustainablitiy of priority elements.

D. Residual Rights. Except as expressly limited by this Easement, Grantor may exercise and enjoy all rights as owner of the Property, including the right to use the Property for any purpose not inconsistent with this Easement.

SECTION IV - NOTICE

A. Form. Whenever a provision is made under this Easement for giving any notice, the notice shall be deemed to have been given if personally delivered, with signed receipt, or mailed by the U.S. registered or certified mail, return receipt requested, addressed to the Party entitled to receive it at the address indicated below, or at another address provided from time to time. If either Party is required to obtain the other Party's prior written approval before performing any act or undertaking any enterprise, then the Party desiring to undertake any such act or enterprise shall not do so until the party has satisfied the notice provisions of this section and prior approval provisions of Section V herein.

B. Notice to Grantor: P.O. Box 670, Grass Valley, California, 95945, or to such other address as the Grantor may designate in writing.

C. Notice to Grantee: P.O. Box 2088, Nevada City, California, 95959, or to such other address as the Grantee may designate in writing.

SECTION V - PRIOR APPROVAL OF ACTIONS BY GRANTEE

042858 013132

A. Grantor's Written Notice. Prior to the commencement of any activity, use, or enterprise which requires Grantee's approval, Grantor will notify Grantee in writing, as set forth in Section IV herein. Such notice must detail the timing, scope, methods and anticipated results of any proposed activity.

B. Grantee's Written Response. The Grantee shall have thirty (30) days from the date that it receives such notice, as indicated by the registered or certified return receipt, to review the proposed activity, use, or enterprise, and pursuant to the notice provisions set forth in Section IV herein, to notify Grantor of Grantee's approval of and/or any objections that Grantee may have to the proposed activity, use or enterprise. Objections, if any, shall be based upon Grantee's opinion that the proposed activity, use or enterprise is inconsistent with the purpose and/or provisions of this Easement. If, in the Grantee's judgment, the proposal set forth by Grantor can be modified to conform with the purposes and provisions of this Easement, then the same response shall inform Grantor of the manner in which the proposed activity can be modified to be consistent with this Easement. Except as provided in Paragraph C of this Section, Grantor can commence or conduct the proposed activity, use, or enterprise only if it receives Grantee's express written approval, and only in the manner explicitly proposed by Grantor and approved by Grantee.

In the event it is Grantee's opinion that the proposed activity is objectionable, based on the foregoing criteria, then, and in that event, Grantee shall make a good faith effort to advise Grantor how the proposal set forth by Grantor can be modified to conform with the purposes of the provisions of the conservation easement. The written response from Grantee shall then inform Grantor of the manner in which the proposed activity can be modified to be consistent with the conservation easement.

C. Grantee's Failure to Respond. If the Grantee fails to provide a written response, as provided under Section IV herein, to a written proposal properly sent to Grantee by Grantor, within thirty (30) days after Grantee receives the proposal, then the proposed activity, use or enterprise automatically shall be deemed consistent with the terms of this Easement, subject to the provisions set forth at Section XII(N) herein, and Grantee will have no further right to object to the activity described in the proposal.

D. Acts of God. Grantor will not be obligated to send any notice to Grantee, and Grantee will not be entitled to bring any action against Grantor, with respect to any reasonable and prudent activity undertaken by Grantor in a good faith effort to prevent, abate, or mitigate injury to the Property from fire, flood, storm, earth movement, acts of war, and similar causes beyond the control of Grantor.

## SECTION VI - PROHIBITED USES AND PRACTICES

The Grantor states and agrees that the following prohibited uses and practices are not inclusive of all prohibited uses and practices, are illustrative of prohibited

~~042858~~ 013132

uses and practices that are presently or hereafter recognized by Grantee as being inconsistent with the purposes of this Easement and shall be strictly prohibited:

A. Introduction of non-native plant and animal species.

B. Erection or placement of any utilities, billboard, sign, fence or structure of any kind on, in or above the Property except with prior written approval by Grantee.

C. Deposition of any soil, trash, ashes, garbage, waste, landfill or any other toxic, noxious or objectionable material.

D. Excavation, dredging or removal of loam, gravel, soil, rock, sand or other material; building of any roads or trails; or any other change, temporary or permanent, in the general topography of the land, except with prior written approval by Grantee. Under no circumstance may any roadway or trail interfere with movement, nesting, forage or other normal activities and behaviors of animals on the Property or with the normal growth of plants on the Property as agreed upon by the Grantee.

E. Placement on, in or above the Property of advertising of any kind or nature whatsoever..

F. Activities, action or uses detrimental to water conservation, erosion control, soil conservation, or fish and wildlife habitat preservation as so determined by Grantee in its reasonable judgment..

G. Livestock grazing.

H. Construction of or placement of fences, except, with the prior written permission of Grantee, such fences as specifically have a maximum of four strands of smooth wire, a bottom wire no lower than 18 inches from the ground and an upper wire not higher than 421 inches from the ground.. No fences shall be built by Grantor on or over the Property in any event except within 2 feet of the Property boundary line or roadway edge. Under no circumstances may any fence interfere with movement, nesting, forage, and other normal activities and behaviors of animals on the Property or with the normal growth of plants on the Property.

I. Cutting, destroying, or removing trees, brush or other vegetation, except as necessary for public safety or the health of the Property as determined by Grantee and with the prior written approval by Grantee.

J. Construction or placement of any recreational facilities, including, but not limited to, picnic tables, campfire rings, barbecue facilities, camping accommodations, or sports fields, on the Property except with the prior written approval by Grantee and consistent with the approved Management Plan.

042858 013132

SECTION VII - BREACH AND RESTORATION

A. Notice and Remedy. If a violation of any restriction contained in Section VI of this Easement, whether by Grantor or by a third party, comes to the attention of Grantee, Grantee promptly shall notify Grantor, as provided in Section IV herein, of such violation. Grantor shall have thirty (30) days after receipt of such notice to undertake actions, including restoration of the Property, that are reasonably calculated to swiftly correct or otherwise remedy the effects, impacts and or conditions caused by such violation. If Grantor fails to take such corrective action, within thirty (30) days, Grantee may at its sole discretion, undertake such actions, including appropriate legal proceedings, as are reasonably necessary to effect such corrections, and the reasonable cost of such corrections, including Grantee's expenses, court costs, and legal fees, shall be paid by Grantor, provided Grantor is determined to be responsible for the violation as finally judged by a court of competent jurisdiction..

B. Restoration. Grantor and the Grantee further intend that should Grantor undertake or cause to be undertaken any activity which requires the prior approval by Grantee without so obtaining such prior approval by Grantee in the manner specified herein, then Grantee shall have the right to force the restoration of the Property affected by such activity to a condition similar or equivalent to the condition that existed prior to the undertaking of such unauthorized activity, by restoring soils, replanting suitable domestic vegetation, or taking such other action as Grantee deems necessary to achieve restoration. In such case, the costs of such restoration and Grantee's expenses, including but not limited to costs of suit and legal fees, shall be borne by Grantor or those of its successors or assigns against whom a judgment is entered, or in the event that Grantee secures redress without a complete judicial proceeding, by Grantor or those of its successors or assigns who are otherwise determined to be responsible for the unauthorized activity. Nothing contained in this Easement shall be construed to preclude Grantor from exhausting its legal remedies in determining whether the proposed activity to which Grantee has objected is inconsistent with this Easement. The parties hereto covenant and agree that the obligation to restore the Property to its prior condition, as provided in this Section VII, may be enforced only against that party or parties who shall have caused such damage, including, but not limited to Grantor and the heirs, personal representatives, successors or assigns of Grantor.

SECTION VIII - REAL ESTATE TAXES

Grantor agrees to pay any and all real property taxes and assessments levied by any competent authority on the Property.

~~012858~~ 013132

SECTION IX - INDEMNITY

Grantor agrees to bear all costs of operation, upkeep and maintenance of the Property, and agrees to indemnify Grantee against all claims and obligations arising from such operation, upkeep, and maintenance activities.

SECTION X - ASSIGNMENT OF EASEMENT

Grantee may not transfer or assign its interest in the Property created by this Easement except to a "qualified organization" (within the meaning of Section 170 (h) (3) of the Internal Revenue Code) which is organized or operated primarily or substantially for one or more of the conservation purposes specified in Section 170 (h) (4) (a) of said Code. Any such "qualified organization" shall agree to enforce the conservation purposes protected by this Easement. Grantee agrees that it will make a reasonable effort in the event of any assignment to choose an assignee which is a qualified organization other than a governmental unit referred to in Section 170(c) (1) of the Code, which has conservation of natural resources as a substantial organizational purpose and provided further, that Grantee represents to the Grantor that its present intention is to assign its interest in this Easement only in connection with a dissolution of Grantee.

SECTION XI - BASELINE DATA

Grantee acknowledges that a preliminary inventory of biological resources and physical condition relating to the Property (the Baseline Data") has been completed by competent naturalists familiar with the Property. Copies of the Baseline Data are on file in the Grantee's offices in Nevada City, California. The Parties acknowledge that the purpose of the Baseline Data is to identify and document the condition of the Property as of the date of the execution of this Easement. In the event of a controversy arising with respect to the nature of the biological and/or physical condition of the Property, neither Party shall not be foreclosed from obtaining, producing or procuring any and all other relevant or material documents, surveys, reports and other information to assist in the resolution of such controversy.

SECTION XII - MISCELLANEOUS PROVISIONS

A. Amendment. Nothing in this Easement shall be construed to preclude Grantor from making a subsequent conveyance of rights in the property to further protect its conservation values, provided, however, that any such subsequent conveyance shall not impair any conservation purpose sought to be advanced by this Easement.

B. Binding Effect; No Third Party Benefits. This Easement shall be binding on all successors and assigns of both Parties and inure to the benefit of the respective successors and assigns of both Parties. Nothing in this Easement shall be

~~042858~~ 013132

deemed to create rights in or benefits for any third parties. Each assignee or purchaser must agree to be bound by the terms of this Easement.

C. Condemnation. If the easement is taken, in whole or in part, by exercise of the power of imminent domain, Grantee shall be entitled to compensation in accordance with applicable law.

D. Enforcement. Grantor intends that enforcement of the terms and provisions of this Easement shall be at the discretion of Grantee, and that Grantee's failure to exercise its rights under this Easement in the event of any breach of this Easement by Grantor shall not be deemed or construed to be a waiver of Grantee's rights under this Easement in the event of any subsequent breach.

E. Estoppel Certificates. Upon request by Grantor, Grantee shall within twenty (20) days execute and deliver to Grantor any lawful document, including an estoppel certificate, which certifies Grantor's compliance with any obligation of Grantor contained in this Easement and otherwise evidences the status of this Easement as may be requested by Grantor.

F. "Grantor" and Grantee". The terms "Grantor" and "Grantee", as used in this Easement, and any pronouns used in place thereof, shall mean and include the above-named Grantor, and its heirs, personal representatives, executors and assigns, and the Nevada County Land Trust, and its successors and assigns, respectively.

G. Liberal Construction. Any general rule of construction to the contrary notwithstanding, this Easement shall be liberally construed in favor of the grant to effect the purpose of appropriate California state code and the conservation purposes set forth above. If any provision in this instrument is found to be ambiguous, an interpretation consistent with the purpose of this Easement that would render the provision valid shall be favored over any interpretation that would render it invalid.

H. Partial Invalidity. If any provision of this Easement or the application of this Easement to any person or circumstance is found to be invalid, the remainder of the provisions of this Easement, and the application of such provisions to persons or circumstances other than those as to which it is found to be invalid, shall not be affected thereby.

I. Recordation. Grantee shall record this instrument in timely fashion in the official records of Nevada County, California, and may re-record it at any time as may be required to preserve Grantee's rights in this Easement.

J. Subsequent deeds. Grantor agrees that reference to this Easement will be made in any subsequent deed, or other legal instrument, by means of which Grantor conveys any interest in the Property (including any leasehold interest), and that a copy of this Deed of Conservation Easement will be attached thereto.

~~042858~~ 013132

K. Titles. Section and paragraph titles and subtitles are for convenience only and shall not be deemed to have legal effect.

L. Waiver of Certain Defenses. Grantor hereby waives any defense of laches, estoppel, or prescription.

M. Waiver of Rights. Any waiver of any of the terms hereof shall be enforceable only to the extent it is waived in a writing signed by the Party against whom the waiver is sought to be enforced. Any waiver shall be only effective for the particular instance for which it is granted and shall not constitute a waiver of a subsequent occurrence of the waived event not constitute a waiver of any other provision hereof, at the same time or subsequently.

IN WITNESS WHEREOF, Grantor and Grantee have executed this Easement on November 30 1999

MGC1 D. STEWART COMM. # 1256809 NOTARY PUBLIC-CALIFORNIA NEVADA COUNTY COMM. EXP. MARCH 24, 2004 MGC1

013132

A portion of the lands situated in the County of Nevada, State of California conveyed by John L. Wilcox and Evangeline H. Wilcox, husband and wife, and Lee D. Roark and Dorothy A. Roark, husband and wife, to Robert T. Roark, Trustee U/D/T dated April 13, 1984 as to a 1/2 interest, and John P. O'Brien as to a 1/2 interest, by Grant Deed dated May 15, 1987 and recorded May 18, 1987, as File No. 87-13323 of Official Records of Nevada County, said lands being within the South half of Section 26, Township 16 North, Range 8 East, M.D.M., said portion being more particularly described as follows:

COMMENCING at a point from which the South one quarter corner of said Section 26 bears South 01° 25′ East 693.00 feet, said point being a corner on the Northerly line of that certain parcel of land conveyed to the State of California, by Deed recorded March 10, 1975, in Book 730, of said Official Records at Page 633, being also an angle point on the Southerly line of the lands described in said Grant Deed recorded as File No. 87-13323;
thence from said POINT of COMMENCEMENT along said Northerly and Southerly line North 89° 30′ 27″ East 516.02 feet to the TRUE POINT OF BEGINNING of the herein described parcel;
THENCE leaving said Northerly and Southerly line North 211.16 feet
thence North 80° 14′ 51″ East 89.48 feet;
thence South 81° 22′ 43″ East 270.59 feet;
thence North 20° 30′ 29″ East 200.00 feet;
thence South 69° 29′ 31″ East 111.05 feet;
thence North 89° 39′ 06″ East 312.77 feet;
thence South 87° 52′ 00″ East 167.90 feet;
thence North 81° 58′ 28″ East 165.06 feet more or less to the Easterly line of the lands described in said Grant Deed recorded as File NO. 87-13323;
thence along said Easterly line South 07° 56′ West 346.51 feet to the above referenced Northerly and Southerly line, said point being marked with a "T" rail on a North line of the Town Talk Placer Mine according to said Grant Deed recorded as File No. 87-13323;
thence along said Northerly and Southerly line South 89° 30′ 27″ West 1126.00 feet to the TRUE POINT OF BEGINNING.

The above described parcel contains 7.65 acres more or less.

This property description has been prepared by me, or under my direction, in conformance with the Professional Land Surveyor's Act.

## GROUP LETTER 2: ERIN TARR, BEAR YUBA LAND TRUST

### Response to Comment Grp 2-1

This is an introductory comment and does not provide a comment on a specific environmental issue associated with the project. Comment noted.

### Response to Comment Grp 2-2

This is an introductory comment recognizing the existence and location of the Bennett Street Grasslands conservation easement and does not provide a comment on an environmental issue associated with the project; rather, the comment expresses general concerns regarding the project's impacts to the 7-acre Bennett Street Grasslands Conservation Easement. The commenter provides specific concerns in the following sections of the letter. Please see the below responses to comments.

### Response to Comment Grp 2-3

This is an introductory comment outlining the commenter's legal obligations to the Bennett Street conservation easement and generally expresses concern that the DEIR does not recognize the conservation easement in the environmental setting and land use sections. The commenter is correct that the Bennett Street conservation easement is not specifically identified in the DEIR, but incorrectly assumes this means impacts to surrounding land uses were not analyzed. The DEIR addresses impacts to surrounding receptors and land uses where appropriate and dependent on the specific resource analysis. For example, the aesthetics analysis analyzes impacts to the surrounding viewshed through visual simulations from those viewpoints. The hydrology analysis looks at both groundwater impacts to surrounding well owners and impacts associated with discharge to South Wolf Creek on the water quality and sedimentation. In addition, the biology section analyzes impacts to transitory species such as birds, raptors, and other wildlife that could exist in the region. As a result, the DEIR correctly analyzes the proposed project's impacts on the environment and is not required to analyze how the project may affect legal obligations of surrounding landowners. The commenter also does not explain how the project conflicts with any of the listed policies.

Regarding the commenter's concerns about the project's potential to impact the water quality and quantity in South Wolf Creek, please see Master Response 35 – Discharge to South Fork Wolf Creek, and Master Response 36 – Flows in South Fork Wolf Creek.

### Response to Comment Grp 2-4

The commenter raises various general comments regarding certain special-status and migratory species that may be impacted by the project and the potential for offsite impacts due to South Wolf Creek discharge. The commenter does not offer evidence of any specific impact, but speculates that an impact could result. However, as stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." Please see Master Response 37 - Birds and Raptors, addressing general comments concerning the olive-sided flycatcher (*Contopus cooperi*), yellow-breasted chat (*Icteria virens*), and yellow warbler (*Setophaga petechia*). Please see Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog, regarding impacts to amphibian species. Please see Master Response 36 - Flows in South Wolf Creek, Master Response 32 - Temperature of Mine Water

Discharge, and Master Response 35 - Discharge to South Wolf Creek, regarding the discharge flow volumes, temperature, and quality, potential for erosion, and species impacts. Regarding benthic macroinvertebrates, please see Response to Comment Grp 31-12.

## Response to Comment Grp 2-5

The Bennett Street Grasslands are located in "Reach D" of the geomorphic assessment for South Fork Wolf Creek. Proposed discharge from the project to South Fork Wolf Creek would range from 1.9 cfs to 5.6 cfs. As shown in Table 5.5 of Appendix K.1 of the DEIR, an increase from 2 cfs to 6 cfs (4 cfs increase) would increase the depth of water from approximately 0.69 ft to 0.91 ft (2.6 inches increase in depth). At 10 cfs the max depth is estimated at 1.09 feet. The discharge would result in a minor increase in water depth and total water depth would be less than a "bank full" event which is estimated at a depth of approximately 1.3 ft for Reach D (See Table 5.1 of Appendix K.1). Bankfull is a term used to characterize the channel dimensions of the channel under the most frequent flows (between a 1- and 2-year flood) identified by change in bank slope, vegetation, or absence and presence of sedimentation. The high-water mark depth for Reach D is approximately 5.6 feet (See Table 5.1 of Appendix K.1). The project would not result in water levels in the Creek exceeding a normal bankfull event or flooding outside of the creek channel and therefore would not affect vegetation adjacent to the creek or interrelated habitat. A series of master responses have been prepared to address potential impacts associated with treated water discharge into South Wolf Creek. Please see:

- Master Response 36 - Flows in South Wolf Creek and Wolf Creek,
- Master Response 32 - Temperature of Mine Water Discharge,
- Master Response 35 - Discharge to South Wolf Creek, and
- Master Response 33 - Groundwater Dependent Vegetation

## Response to Comment Grp 2-6

The CEQA guidelines require analysis of substantial interference to "the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites." Migration is defined as the seasonal movement of animals from one habitat to another. Various animal, bird, and fish species are not automatically considered migratory just because they move from one location to another. Migration serves a purpose for the species such as winter/summer habitat for foraging or breeding. It is acknowledged, and analyzed in the DEIR impact analysis (see Section 4.4.4), that species exist within the project site that are common to the area. Potential impacts to these species were analyzed and mitigation measures have been provided where it was determined impacts to species could occur as a result of project activities, including preconstruction surveys and agency permitting. The only migratory species acknowledged by the County General Plan is deer migration corridors. Impact 4.4-4 addressed the project's impact to this potential migratory corridor and concluded it would be less than significant. The commenter does not raise any specific impact that would be caused by the project, but speculates that impacts could result. CEQA does not require analysis of speculative impacts. (CEQA Guidelines Section 15384.)

In addition, the commenter identifies South Fork Wolf Creek as a vital wildlife movement corridor that could be affected by changes in water quantity and quality. For these concerns, please see Master Response 35 – Discharge to South Fork Wolf Creek and Master Response 36 – Flows in South Fork Wolf Creek. It is also noted that DEIR Impact 4.4-3 requires the preparation of aquatic resources management plans that will mandate setbacks and other requirements to minimize

impacts to Wolf Creek, South Fork Wolf Creek, and surrounding habitat, which is consistent with General Plan Policy 13.1 (i.e., retain non-disturbance open space to promote continued viability of contiguous or inter-dependent habitats by avoiding fragmentation of existing habitat areas and preserving movement corridors between related habitats). Draft management plans were included as Appendices F.5 and F.8.

## Response to Comment Grp 2-7

The commenter asserts that there is no surface water quality baseline data presented in the DEIR. However, this is incorrect, as sampling was performed within South Fork Wolf Creek (See Master Response 35 – Discharge to South Fork Wolf Creek) to ascertain existing water quality in the creek. The commenter requests that specific samples be taken from South Fork Wolf Creek to establish baseline water quality; however, as discussed above, sufficient sampling has already been conducted to analyze the project's potential water quality impacts.

## Response to Comment Grp 2-8

The commenter asserts that the DEIR Project Description did not provide enough detail on how water discharged into South Fork Wolf Creek would not cause a significant impact to water quality. However, the Project Description is not the portion of the DEIR that analyzes project impacts; rather the project's potential water quality impacts are analyzed in detail in Chapter 4.8 of the DEIR. As discussed in great detail in Chapter 4.8 of the DEIR, the project may have a potentially significant impact on water quality and therefore Mitigation Measure 4.8-1(a) is required to address these potential impacts. This mitigation measure requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. The NOI shall include evaluation of potential constituents of concern and demonstrate that the water treatment plant (WTP) design shall successfully treat mine water to meet the water quality standards and treatment goals.

Please see Master Response 32 - Temperature of Mine Water Discharge, Master Response 35 - Discharge to South Fork Wolf Creek, and Master Response 36 - Flows in South Fork Wolf Creek.

The commenter states that there is substantial evidence showing that the creek's water quality would be adversely affected by the project-generated surface water run-off and that total maximum daily load (TDML) was not used to measure this project impact. The commenter does not provide this substantial evidence, specify what surface runoff would affect the creek's water quality, or the commenter's definition of TDML and how the project impact would be measured and analyzed by TDML. In regard to surface water runoff from engineered fill, please see Master Response 8 - Mine Waste Characterization. Mitigation Measures 4.8-1(b) and 4.8-1(c) require Construction and Industrial Stormwater Pollution Prevention Plans (SWPPP). As discussed in Chapter 4.8 of the DEIR and stated on page 4.8-49 of the DEIR, SWPPP would address any activities that would have the potential to release pollutants to stormwater, including material and chemical storage, vehicle operation and maintenance, and material handling and transport.

## Response to Comment GRP 2-9

DEIR Section 4.8.4, Impact 4.8-1, analyzed the proposed project's impacts on water quality and determined project construction could result in a potentially significant impact. The DEIR requires a construction stormwater prevention and pollution plan as Mitigation Measure 4.8-1, which reduces the impact to a less than significant level. The County has a mitigation monitoring and

reporting program included with the Final EIR, which will allow the County to have monitoring and enforcement authority over project mitigation and conditions of approval. The commenter's assertion that the applicant would fail to comply with the storm water pollution prevention plan is speculative, and CEQA does not require analysis of speculative impacts. Moreover, the County and RWQCB have enforcement authority over the mine operator's implementation of the SWPPP.

## Response to Comment Grp 2-10

The commenter points to the League to *Save Lake Tahoe Mountain Area Preservation Foundation v. County of Placer* (2022) 75 Cal.App.5th 63, court decision to support its assertion that the DEIR is inadequate. Specifically, the commenter asserts that the DEIR does not provide adequate baseline description, methodology, cumulative impacts analysis and adequate mitigation measures. The environmental baseline is provided in extensive detail in each resource section of the DEIR; cumulative impacts are analyzed throughout the DEIR for each resource area; and the DEIR includes numerous mitigation measures designed to reduce impacts where feasible. The present project is distinguishable from the project in the cited case, and the commenter provides no specific example of how they are similar.

## Response to Comment Grp 2-11

The commenter states that a combination of Alternative 2 and Alternative 4 should be considered, which would eliminate placement of fill material on the Centennial Site but also reduce extraction as proposed in Alternative 4. Section 6 of the DEIR considered project alternatives. As summarized in DEIR section 6.2, and provided in CEQA Guidelines section 15126.6, an EIR shall provide a reasonable range of alternatives that achieves the project objectives but avoids or reduces significant project impacts. The alternatives analysis is not required to consider every project alternative but is governed by a "rule of reason" that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice." The alternative analysis in the DEIR considered nine different alternatives. Five alternatives were considered but rejected from detailed analysis since they did not meet most project objectives, were infeasible, and/or did not avoid significant project impacts. Four alternatives were analyzed in detail (see DEIR section 6.3.) The County believes this provides a reasoned choice of alternatives for consideration by the public and decisionmakers. The Alternative proposed by the commenter is not anticipated to eliminate any of the significant impacts of the project, and would also lessen the project's benefits by reducing employment and making the project less financially feasible.

## Response to Comment Grp 2-12

Please see Master Response 1 - Non-EIR/Administrative Issues.

## Response to Comment Grp 2-13

The comment generally summarizes the content of the letter. Please see Responses to Comments Grp 2-2 through Grp 2-12. Please also see Master Response 1 - Non-EIR/Administrative Issues.

**Group Letter 15**

March 31, 2022

Nevada County Board of Supervisors
950 Maidu Avenue, Suite 200
Nevada City, CA 95959

Dear Supervisors Sue Hoek, Heidi Hall, Ed Scofield, Dan Miller and Hardy Bullock:

As Board Directors, entrusted with the representation of over 8,000 BriarPatch Co-op owner-members, we are writing to express our opposition to the proposed reopening of the Idaho-Maryland Mine by Rise Gold Corp.

**Grp 3-1** BriarPatch is driven by Ends Policies which include environmental stewardship, a stronger local food system, and a community-focused healthy workplace. We are deeply committed to improving the quality of life for our shoppers and staff. Rise Gold plans and their Draft Environmental Impact Report contain several troubling aspects that are counter to these unwavering values.

**Grp 3-2** This project is expected to use 12% of Nevada County's electrical supply, more than all the rest of the County's businesses combined. We have worked hard as an organization toward a net zero energy goal and are inspired to see the county reduce their carbon footprint as well. This would erase all gains made toward that end. Additionally, with PSPS and catastrophic weather events, we question the judgement of one single business using so much energy, thus compromising the grid.

**Grp 3-3** With an alarming drought, there are serious concerns about our watershed. The Co-op has implemented strategies that have saved an average of 150,000 gallons each month. Rise Gold plans on pumping more than a million gallons a day for decades. Further, we are very concerned about

**Grp 3-4** arsenic, ammonia, and other contaminants from treated mine wastewater polluting downstream irrigation water and prohibiting farm use. Self-monitoring of water quality is not a high enough bar for Rise Gold, especially given the track record of the company's CEO.

**Grp 3-5** Air quality is another major concern, especially during peak fire season. Rise Gold's 'dump site' is just a mile from the Co-op's front door and there will be atmospheric exposure to employees, as well as shoppers. The safety of our staff is of the highest priority. Our owner-members are very health conscious and we do not want their shopping experience polluted.

**Grp 3-6** As you review public comments on this issue, we urge you to consider what is best for the quality of life for the residents of this community. We ask that you vote against approval of the mine, affirming your contract with your constituency that you are acting in the best interest of all.

BriarPatch Food Coop * 290 Sierra College Drive * Grass Valley CA 95945

Sincerely,

Alana Lucia, Board President

Rachel Berry, Board Vice-President

Katie Ivy, Board Secretary

Mark Fenton, Board Treasurer

Kwong Chew, Board Director

Jonathan Collier, Board Director

Kali Feiereisel, Board Director

Richard Drace, Board Director

Alan Weisberg, Board Director

Cc: Nevada County Planning Commission (Suite 170)

BriarPatch Food Coop * 290 Sierra College Drive * Grass Valley CA 95945

## GROUP LETTER 3: MARY HUNTER, BRIARPATCH FOOD CO-OP

### Response to Comment Grp 3-1

The commenter's opposition to the proposed project is noted for the decisionmakers. Please see Master Response 1 - Non-EIR/Administrative Issues.

### Response to Comment Grp 3-2

This commenter is concerned with the electrical power usage associated with the project and that it would negate progress towards net-zero energy goals. The commenter is also concerned with Public Safety Power Shutoffs (PSPS) and catastrophic weather events.

The commenter is correct that the proposed project would create new demand for energy resources. However, the threshold for significance for energy impacts established by CEQA Guidelines Appendix G is not whether a project would use energy, but whether a project would use energy in an inefficient or wasteful manner. The DEIR's discussion of Impact 4.3-4 summarizes the various measures that would be implemented to reduce the project's energy demand including the use of high-efficiency off-road equipment, the use of Tier 4 Final compliant engines for emergency generators, and fleet compliance with federal and state fuel efficiency standards. (DEIR, p. 4.3-86–88.) The DEIR concludes that implementation of these measures would ensure that the project does not result in the inefficient or wasteful use of energy and the impact would be less than significant. Please also see Response to Comment Agcy 8-17. Furthermore, Impact 4.3-10 determined that the project would not conflict or interfere with any State adopted plans for renewable energy production or energy efficiency. (DEIR, p. 4.3-88–90.)

CEQA Guidelines Appendix G also determines the significance of impacts based on whether a project requires or results in the relocation or construction of new or expanded electrical power facilities. (DEIR, p. 4.11-19.) The DEIR found that impacts related to requiring the relocation or construction of new or expanded electrical power facilities would be less than significant. (DEIR, p. 4.11-31.) The electrical grid system in the project area is well developed and PG&E has provided a will serve letter for the project. (DEIR, p. 4.11-35.) The commenter provides no evidence to support its statement that the project would "compromise" the electrical grid.

The portion of the comment regarding the potential for catastrophic weather events to compromise the power-grid does not address the adequacy of the DEIR and does not warrant further response but is noted for the decisionmakers.

### Response to Comment Grp 3-3

This comment expresses concern regarding the area's watershed and the project's anticipated water demands in light of the drought that California is experiencing.

Regarding the project's anticipated water demands for both potable and non-potable uses, the DEIR found that there are sufficient water supplies available to serve the proposed project as well as existing and reasonably foreseeable future development during normal, dry, and multiple dry years and that the project's impacts to water supplies would be less than significant. (DEIR, p. 4.11-43). The DEIR evaluates the project's potential impacts on groundwater resources (see Impact 4.8-2 on DEIR pages 4.8-54 through -68) and concludes that with implementation of Mitigation Measures 4.8-2(a) through 4.8-2(c), impacts to groundwater supplies would be less than significant. The DEIR further evaluates the sufficiency of available water supplies to meet

the project's demands (see Impact 4.11-7 on DEIR pages 4.11-35 through -43) and concludes that available supplies would be sufficient, and no mitigation is required.

## Response to Comment Grp 3-4

The commenter is also concerned with contaminants in the treated mine wastewater and that self-monitoring is insufficient given the "track record of the company's CEO."

Please see Master Response 35 regarding the discharge to South Fork Wolf Creek. The DEIR found any impacts associated with violation of any water quality standard or waste discharge requirements would be less than significant after mitigation. (DEIR, p. 4.8-41.) Impact 4.8-1 in the DEIR addresses the potential for project wastewater to contain elevated levels of relevant contaminants. (DEIR, p. 4.8-41–53.) The DEIR acknowledges that the "proposed project's construction and operations involve multiple activities that could result in adverse effects to water quality." (DEIR, p. 4.8-51.) However, the project's "proposed water management and treatment, and adherence to permit requirements [of the RWQCB] would avoid significant impacts to water quality…" (DEIR, p. 4-8.51.) The DEIR describes the specific requirements for regulatory compliance in Mitigation Measures 4.8-1(a) through 4.8-1(e). Coverage under the Limited Threat Discharge permit would require ongoing water quality sampling and testing, with oversight by the RWQCB, to demonstrate that the proposed water treatment plant is successfully treating mine water to meet the water quality standards and treatment goals of the permit. All samples, data and analysis would be verified and evaluated by qualified RWQCB staff, and the RWQCB would have enforcement authority.

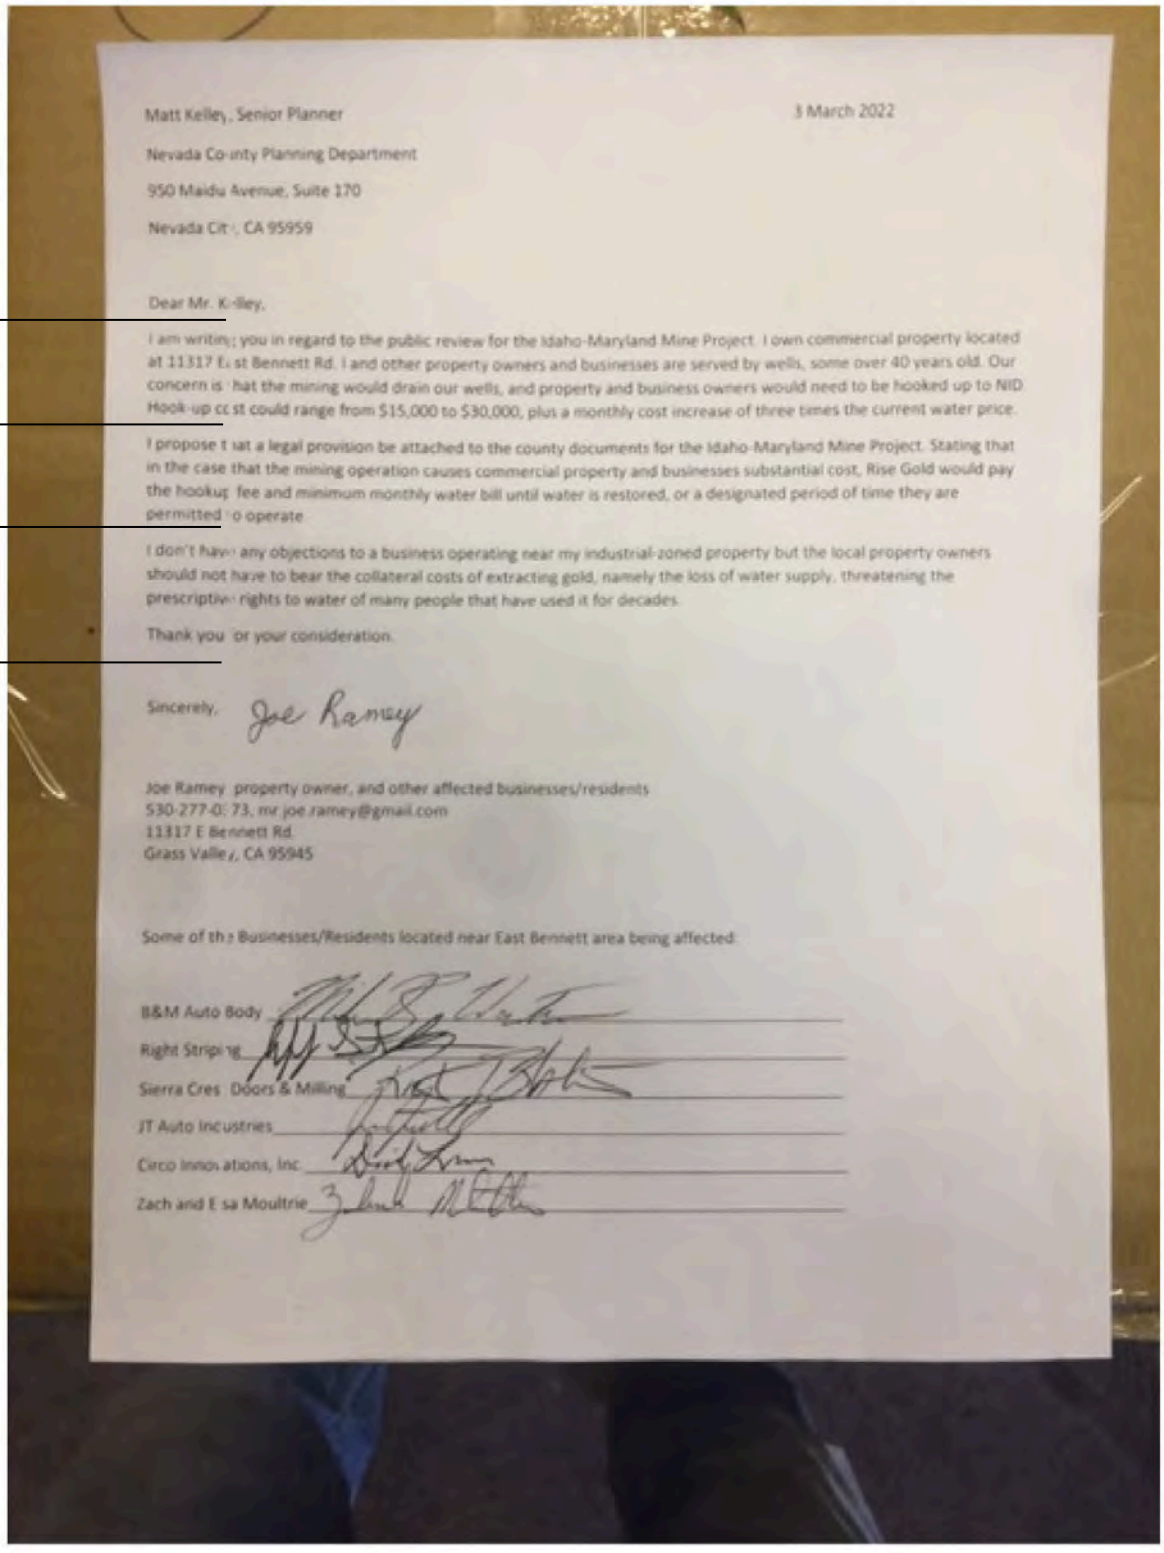
While comments related to the CEO of the Project Applicant are not relevant for CEQA purposes, this topic is addressed in Master Response 3 – Operator Responsibility.

## Response to Comment Grp 3-5

The commenter is concerned with the air quality impacts of the project, especially during peak fire season.

The DEIR addresses potential air quality impacts of the proposed project in Chapter 4.3, "Air Quality, Greenhouse Gas Emissions, and Energy" and found that impacts associated with air quality would be less than significant after mitigation. (DEIR, 4.3-66, -78, -84.) Specifically, Impact 4.3-2 addresses the potential to expose sensitive receptors to substantial pollutant concentrations. (DEIR, 4.3-78–84.) The DEIR concludes that "project-related CO emissions would not exceed the one-hour or eight-hour thresholds, and, as such, the project would not expose sensitive receptors to excess concentrations of CO." (DEIR, p. 4.3-82.) The DEIR further demonstrates "that emissions of [toxic air contaminants] would not result in health risks to nearby receptors in excess of NSAQMD thresholds. Furthermore, criteria pollutant emissions from project construction, operations, and reclamation would not expose receptors to substantial concentrations of pollutants." (DEIR, p. 4.3-82.) Mitigation Measure 4.3-2 addresses the potential for exposure to existing levels of asbestos in project site fill materials by requiring development and implementation of an Asbestos Dust Mitigation Plan. (DEIR, p. 4.3-82.) With implementation of this mitigation measure, the impacts to air quality would be less than significant. Please also see Master Response 18 - Air Quality Thresholds, and Master Response 19 – NSAQMD Criteria Pollutant Thresholds during Operations.

## Response to Comment Grp 3-6



The commenter's opposition to the project is noted for the decisionmakers. The commenter is referred to Master Response 1 - Non-EIR/Administrative Issues.

**Grp 4-1**

**Grp 4-2**

**Grp 4-3**

Matt Kelley, Senior Planner

3 March 2022

Nevada County Planning Department

950 Maidu Avenue, Suite 170

Nevada City, CA 95959

Dear Mr. Kelley,

I am writing you in regard to the public review for the Idaho-Maryland Mine Project. I own commercial property located at 11317 East Bennett Rd. I and other property owners and businesses are served by wells, some over 40 years old. Our concern is that the mining would drain our wells, and property and business owners would need to be hooked up to NID. Hook-up cost could range from $15,000 to $30,000, plus a monthly cost increase of three times the current water price.

I propose that a legal provision be attached to the county documents for the Idaho-Maryland Mine Project. Stating that in the case that the mining operation causes commercial property and businesses substantial cost, Rise Gold would pay the hookup fee and minimum monthly water bill until water is restored, or a designated period of time they are permitted to operate.

I don't have any objections to a business operating near my industrial-zoned property but the local property owners should not have to bear the collateral costs of extracting gold, namely the loss of water supply, threatening the prescriptive rights to water of many people that have used it for decades.

Thank you for your consideration.

Sincerely, Joe Ramey

Joe Ramey property owner, and other affected businesses/residents
530-277-0[illegible]73, mr.joe.ramey@gmail.com
11317 E Bennett Rd.
Grass Valley, CA 95945

Some of the Businesses/Residents located near East Bennett area being affected:

B&M Auto Body

Right Striping

Sierra Cres Doors & Milling

JT Auto Industries

Circo Innovations, Inc

Zach and Elsa Moultrie

## GROUP LETTER 4: JOE RAMEY, BUSINESS OWNERS (MULTIPLE SIGNATURES)

### Response to Comment Grp 4-1

The commenter owns property near the project site and is concerned that the dewatering of the mine will impact the groundwater well service the property. Water wells in this area (E. Bennett Industrial Area) have been evaluated in the DEIR and are predicted to experience minimal drawdown of 1 to 2 feet from mine dewatering (see page 79 of Appendix K.2) and no mitigation for these properties is proposed. However, if groundwater monitoring during the initial dewatering determines that mitigation is required for these properties, the Project Applicant would be required to fund the associated costs to connect to NID. The commenter is referred to Chapter 4.8 (Hydrology and Water Quality) of the DEIR and Master Response 15 - Adequacy of Groundwater Monitoring Wells.

### Response to Comment Grp 4-2

The commenter requests that the Project Applicant be required to pay any costs associated with the connection to NID in the event a property's groundwater well is impacted. The mitigation measures for the project already specify the requirements for the applicant to fund any necessary well mitigation. The commenter is referred to Chapter 4.8 (Hydrology and Water Quality) of the DEIR and Master Response 15 - Adequacy of Groundwater Monitoring Wells.

### Response to Comment Grp 4-3

The commenter states that nearby property owners should not have to pay the connection cost to NID as a result of the project. The commenter is referred to Response to Comment Grp 4-1.

**Group Letter 5**

# California Native Plant Society

## Redbud Chapter CNPS

Mr. Matt Kelley
Senior Planner
Nevada County Planning Department
950 Maidu Avenue, Suite 170
Nevada City, CA 95959-7902 (530) 265-1423

Via email: Idaho.MMEIR@co.nevada.ca.us

Dear Mr. Kelley,

Thank you for the opportunity to comment on the Draft Environmental Impact Review for the Idaho Maryland Mine.

This letter, submitted on behalf of the California Native Plant Society and its local Redbud Chapter, is focused on the flaws in the DEIR relating to Biological and Aquatic Resources for the Centennial and Brunswick sites.

**I. The DEIR's use of a project definition that excludes the Centennial Cleanup violates CEQA.**

**Grp 5-1**

The DEIR fails to meet CEQA requirements by omitting the cleanup in its analysis of impacts. Because the preparation for reopening and subsequent operation of the IMM cannot proceed without the cleanup, the two constitute a single project for the purposes of CEQA and their environmental impacts must be analyzed together.

The *Guidelines for Implementation of the California Environmental Quality Act* define the term "project" broadly: "'Project' means the whole of an action, which has a potential for resulting in either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, and that is any of the following: ... (3) An activity involving the issuance to a person of a lease, permit, license, certificate, or other entitlement for use by one or more public agencies." 14 CCR Sec. 15378 (a).

The DEIR has excluded the cleanup of the Centennial site and improperly defined the Idaho Maryland Mine "project" as everything but the cleanup plan that is currently under review by

the Department of Toxic Substances Control ("DTSC"). This is contrary to CEQA: "The term 'project' refers to the activity which is being approved and which may be subject to several discretionary approvals by governmental agencies. *The term 'project' does not mean each separate governmental approval.*" 14 CRR Sec. 15378 (c) (Emphasis added.)

CEQA's broad definition of "project" is intended to prevent "a proponent or a public agency from avoiding CEQA requirements by dividing a project into smaller components which, when considered separately, may not have a significant environmental effect. ..." *Nelson v. County of Kern*, 190 Cal. App. 4th 252 (2010).

In *Nelson*, the Federal Bureau of Land Management had conducted an environmental review of a request for a permit for a surface mining operation and had issued the permit. Kern County then limited its review to a consideration of whether it should approve the reclamation plan for that mine. The Appellate court concluded that the County was required to review "*both* the mining operations and the reclamation plan. Both aspects were integrally related and constituted the whole of the action or the entire activity for which approvals were being sought. ... [T]he reclamation plan was simply the final phase of the overall usage of the land proposed by [the applicant] ... ." 190 Cal. App. 4th 272.

Here, the cleanup is "simply the [first] phase" of the land usage; the mine and the cleanup are "integrally related" and constitute "the entire activity for which approvals [are] being sought."

In treating the cleanup as "separate," the DEIR focuses on "isolated parts of the whole" of the IMM project, "overlooking" and distorting its cumulative impacts and failing to inform the public and decision makers of significant environmental impacts. In so doing, it thwarts the purposes of CEQA. *McQueen v. Board of Directors* (1988) 202 Cal.App.3d 1136, 1144.

This flaw – excluding the Centennial site cleanup from the DEIR's CEQA review – is inherent in the original Notice of Preparation ("NOP") issued July 17, 2020. The NOP declares that that the "project applicant" is working with DTSC to clean up the Centennial site "*separate from the proposed project.*" (Emphasis added) (NOP p. 5)

After declaring the cleanup to be "separate" from the mine, the NOP describes the mine project in such a manner that it is clear the mine is dependent on the cleanup, not a separate project. Thus, the Centennial site "currently cannot be developed" because of contamination caused by historic "deposition of mine tailings on the site" (NOP p. 5), but the IMM will nonetheless (1) use the Centennial site (after the cleanup) for depositing 1.6 million tons of *additional* mine waste, and (2) reclaim the Centennial site for reuse or sale after the mine closes 80 years later.

Specifically, the NOP Site Plan for the Centennial Site calls for 44 acres of the 56-acre site to be buried in new mine waste *after* the cleanup. (NOP p. 2; see also NOP Figure 7, "Site Plan – Centennial Industrial Site") ("Attachment A.") This same Figure is later used in the DEIR (Chapter 3, Page 3-16, Figure 9, "Site Plan").

In addition, the "reclamation plan" described in the NOP notes that after the closure of the mine, the Brunswick and Centennial "fill slopes would be revegetated with an erosion-control seed mix to reduce erosion and maintain fill slope stability. The fill pads would be maintained until they are used or sold for future industrial purposes." (NOP p. 9; see also DEIR Chapter 3, pp. 3-42, 3-46 and 3-47.)

Clearly, neither the dumping of 1.6 million tons of additional mine waste on the Centennial site nor the reclamation of land "to be used or sold for future industrial purposes" after the mine closes is possible without the cleanup. There is no basis whatsoever for the County to claim the cleanup is a "separate" project.

Such a separation of the mine project into arbitrary segments is explicitly forbidden by CEQA. Accordingly, the County's assertion that the cleanup is a "separate project" clearly must fail. The separation of the cleanup from the mine is artificial and misleading.

**II. The CEQA Review of the Cleanup and the Mine Reopening Must Encompass the "Whole Project" and Must Not be Segmented or Reviewed in a "Piecemeal" Manner.**

Under CEQA, "a project must not be broken into smaller parts, each of which alone might qualify for a Negative Declaration, in an attempt to avoid preparing an EIR." Mitigated Negative Declarations, CEQA Technical Advice Series, California Office of Planning and Research, p.2 *https://opr.ca.gov/docs/MND_Publication_2004.pdf. See also Association for Sensible Development of Bishop Area v. County of Inyo* (1985) 172 Cal. App.3d 151.

"CEQA forbids 'piecemeal' review of the significant environmental impacts of a project." *Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners* (2001) 91 Cal.App.4th 1344, 1358. Agencies cannot allow "environmental considerations [to] become submerged by chopping a large project into many little ones—each with a minimal potential impact on the environment—which cumulatively may have disastrous consequences." *Bozung v. Local Agency Formation Com* (Cal. 1975) 13 Cal.3d 263, 284 (superseded by statute on other grounds).

The California Supreme Court set forth a piecemealing test in *Laurel Heights Improvement Assn. v. Regents of University of California* (Cal. 1988) 47 Cal.3d 376. "We hold that an EIR must include an analysis of the environmental effects of future expansion or other action if: (1) it is a reasonably foreseeable consequence of the initial project; and (2) the future expansion or action will be significant in that it will likely change the scope or nature of the initial project or its environmental effects." *Laurel Heights*, 47 Cal.3d 376, 396.

There may be improper piecemealing when the reviewed project legally compels or presumes completion of another action. (*Nelson v. County of Kern* (2010) 190 Cal.App.4th 252, 272 [When reviewing a reclamation plan, the County should have included mining operations

that necessitated it]; *San Joaquin Raptor/Wildlife Rescue Center v. County of Stanislaus* (1994) 27 Cal.App.4th 713, 732 [32 Cal.Rptr.2d 704] [EIR for residential development should have included sewer expansion that was a "crucial element" of development].

Here, the cleanup and the mine reopening application are part of one project requiring a single EIR. The same proponent, Rise Gold, dba Rise Grass Valley (RGV), sponsored the RAP and is also the applicant for the mining permit. The completion of the RAP is a prerequisite to the mine reopening, and the DEIR "presumes" the approval and completion of the RAP. The County has used the separate RAP review not only as a basis to disregard the wetlands and other biological resources at the Centennial site, but also as a tactic to justify using a hypothetical future "adjusted baseline" in the DEIR to avoid any assessment of the true environmental impacts of the mine.

The cleanup has been treated as a separate project even though it is on the same property as the Mine Project, with the same aquatic resources and environmental issues, and despite the fact that the mine cannot be reopened and operated without the cleanup.

Instead, the DEIR conveniently wipes the wetlands off the map. See, for example, DEIR Chapter 4.4 Biological Resources page 4.4-12, Figure C "IMM Project Baseline after DTSC Cleanup" which includes a blank 28-acre area labeled "Clean-up Area – DTSC Project." (Attachment "B")

The separation of the review of the cleanup from the mine project has enabled the County, with the aid of the DTSC, to attempt to evade any meaningful evaluation of the cumulative environmental impacts of the cleanup and the mine on the wetlands, riparian areas, and other important natural resources of the Centennial Site.

The fact that these two environmental reviews are taking place in tandem has obscured the impacts of the mine on aquatic and other biological resources at the Centennial site. The DEIR reflects the fundamental defects of this process; it omits any assessment of major environmental impacts on the Centennial site.

The results of this fragmented process include a DEIR that denies the existence of any protected wetlands and riparian areas at the Centennial site, premised on a flawed draft RAP that has not been approved.

Indeed, if the DEIR and RAP are approved in their current forms, the protected Centennial aquatic resources will be destroyed without any evaluation of environmental impacts. This is a textbook case demonstrating why CEQA policy prohibits "piecemeal" review. The Centennial Site and the Mine project are a single "project" and must be reviewed as such under CEQA. *See Tuolumne County Citizens for Responsible Growth, Inc. v. City of Sonora* (2007) 155 Cal.App.4th 1214, 1222.

**III. The County Improperly defers to DTSC's review of the cleanup as proposed in Rise Gold's Remedial Action Plan (RAP) in its MND.**

Instead preparing its own EIR for the cleanup (as part of this DEIR), the County is deferring to the DTSC's use of a Mitigated Negative Declaration ("MND") process to review the cleanup plan. This amounts to splitting the analysis of the IMM project's environmental impacts across two types of environmental review documents, which is prohibited by CEQA.

The California Court of Appeals in *Farmland Protection Alliance v. County of Yolo* 71 Cal. App. 5th 300 (2021) reaffirmed that "'once evidence is presented that a project might have a substantial impact on the environment -- in any area -- the lead agency *must* proceed to prepare an environmental impact report *'for the proposed project.'* " (Citing *Muzzy Ranch Co. v. Solano County Airport Land Use Com.* (2007) 41 Cal.4th 372.)

An MND is appropriate only if there is no substantial evidence that a project might have a significant effect on the environment. *(Pub. Res. Code Section 21064.5).* Here, there is clearly substantial, indisputable evidence that the mine project "might have a significant effect on the environment." One specific example is the cleanup's environmental impact on the Centennial site wetlands and streams. This substantial evidence was presented during the DTSC process, and in the DEIR (including Appendices) itself.

**Grp 5-2**

The June 19, 2020, *Technical Memorandum for Centennial Industrial Site: Remedial Action Plan Project – Biological Resources Impact Assessment* submitted as part of the DTSC MND review shows that 4.35 acres of the 4.37 acres of mapped wetlands and .19 acres of the .6 acres of mapped streams would be "impacted" by the cleanup project (See p. 7, Tables 3.0 and 4.0 of the Technical Memorandum). At page 13, it is made clear that the wetlands will cease to exist: "Disturbance within the Centennial Industrial Site from the implementation of the RAP Project is estimated to fill a maximum of 4.35 acres of mapped wetlands and 0.19 acres of intermittent and ephemeral streams within the Centennial Industrial Site."

Thus, the plan is to dredge and fill essentially ~~all of~~all the wetlands and almost 30% of the mapped streams on the property. These impacts clearly constitute "significant environmental impacts."

Circulated for comment in July, 2021, the DTSC's draft MND and Draft Final Remedial Action Plan ("RAP") offered no alternatives that would preserve any of the mapped wetlands on the Centennial site. Instead, the plan is to use over 129,000 cubic yards of soil from these *uncontaminated* wetlands and streams as *clean fill* to "cap" and backfill the contaminated areas being remediated. See green dotted line surrounding wetlands on the "Overview of Proposed Remedial Action" map of the Centennial area (RAP Fig. 5). (Attachment "C") This area matches the outline of the "Clean-up Area – DTSC Project" on Attachment B. None of the alternative cleanup plans considered by the RAP called for using offsite sources of "clean fill" so that these wetlands could be preserved. Instead, they are to be destroyed.

Numerous comments on the MND and RAP were submitted, by Redbud CNPS and others, specifically challenging the failure to include the cleanup as part of the DEIR and presenting substantial evidence that the cleanup project as proposed could (and would) have significant environmental impacts in several areas.

Several comments also challenged the failure to consider alternatives that would preserve any portion of the wetlands. The DTSC is still reviewing the draft RAP and consulting with legal counsel, and has not approved the cleanup plan, or selected any of the alternative options described in the draft MND.

Yet the County's DEIR continues to attempt to sever the cleanup from the mine. The January 29, 2021 DEIR Appendix F-3, "Updated Technical Memorandum for Centennial Industrial Site: Idaho-Maryland Mine Project – Biological Resources Impact Assessment" notes in passing the mapped wetlands and streams at the Centennial Site mentioned above, then dismisses them as part of the so-called "separate" cleanup.

"The environmental cleanup work at the Centennial Industrial Site will be completed under the DTSC voluntary cleanup program and is outside the scope of the IMM Project. It is estimated that the cleanup program will cause a surface disturbance of 26.56 acres ... which will incorporate impacts to approximately 4.35 acres of mapped wetlands and 0.19 acres of mapped streams within the Centennial Industrial Site. Therefore, the impacts and associated mitigation of approximately 4.54 acres of wetlands and streams within the Centennial Industrial Site will be incorporated into the DTSC voluntary cleanup project and is outside the scope of the IMM Project." DEIR Appendix F-3 p. 2.

The above statement makes it clear that there will be no remaining wetlands to protect or mitigate on the Centennial site *because the wetlands will no longer exist.* If the plan were to retain any existing wetlands, or to restore or recreate wetlands elsewhere on the site, the DEIR would be required include them in the Updated Technical Memorandum and in the Centennial aquatic resources management plan. It does not.

As noted previously, maps of the on-site Centennial "borrow areas" (the designated sources of the 129,100 cubic yards of "clean fill") make it clear that the fill *will be taken from wetlands and riparian areas, not from other uncontaminated areas of the site.* (See, e.g., Attachment C)

CEQA requires that options to avoid and minimize adverse impacts to uncontaminated wetlands be considered and adopted, unless the impacts are unavoidable. Here, the adverse impacts can be avoided and there are alternatives. Clean fill can be brought in from off-site, or from other areas of the Centennial site, and *the uncontaminated wetlands and riparian areas can be preserved.*

Neither DTSC's Final CEQA Initial Study or the DEIR addresses adverse impacts to the wetlands caused by the cleanup, and there is no analysis of how such impacts can be minimized or avoided.

Instead, the Centennial Biological Resources Impact Assessment (Nov. 12, 2019) states that the mine project *"would have no impact on mapped wetlands within the Centennial Industrial Site* given that *any fill or dredge of mapped wetlands ... will occur as part of the site remediation project approved through DTSC prior to the development of the IMM Project."* P. 5. (Emphasis added.) In other words, there will be no wetlands left after the cleanup, so the EIR for the mine project is not required to identify, analyze, or mitigate any adverse environmental impacts to wetlands.

Thus, the DEIR itself, as well the DTSC MND for the RAP, includes substantial evidence that many aspects of the Centennial cleanup project mandate preparation of a full DEIR. As lead agency, the County cannot ignore that evidence. The County must prepare a new DEIR that analyzes the impacts of the project in its entirety, including both the cleanup and the mine construction and operations.

**IV. The DEIR Fails to Establish an Appropriate Environmental Baseline**

An EIR is required to describe the baseline physical conditions on the project site which the lead agency will use to determine whether an impact is significant. (CEQA Guidelines, §15125(a)(1)). An EIR is deficient when it "completely fails to properly establish, analyze, and consider an environmental baseline." *See Communities for a Better Environment v. City of Richmond*, 184 Cal.App.4th 70, 89 (Cal. Ct. App. 2010). "When an EIR omits relevant baseline environmental information, the agency cannot make an informed assessment of the project's impacts." *Id.*

**Grp 5-3**

This project fails to accurately describe the environmental baseline in several ways: (1) the "adjusted baseline" is speculative, improper, and hides from the public the true environmental impacts to the Centennial site; (2) the DEIR's use of an adjusted baseline for the Centennial Site obfuscates the actual impacts of both the cleanup and the IMM on plants and habitats at both sites; and (3) the Centennial and Brunswick aquatic and biological resources assessments and management plans do not meet CDFW, CNPS, and other protocols and standards. For example, botanical and aquatic resources surveys were conducted late in the summer, outside many plant species' blooming period, and during the dry season when not all species and wetlands would be observable. Accordingly, they cannot be relied on as evidence that all special-status plants and all wetlands on the project site have been identified.

**A. The DEIR's choice of an "adjusted" baseline using only hypothetical future conditions violates CEQA.**

**Grp 5-4**

The DEIR's use of a future "adjusted baseline," set after the cleanup has theoretically been completed, violates CEQA. In general, the baseline for evaluating the environmental impacts of a project is the existing condition of the site. Although a future baseline may be used in addition to the existing conditions when appropriate, the California Supreme Court held in *Neighbors for*

*Smart Rail v Exposition Metro Line Construction Authority* (2013) that a DEIR may not substitute a future baseline for an existing baseline unless there is substantial evidence that using an existing conditions baseline would be "misleading" or "uninformative" to the decision maker and the public.

Here, the reverse is true: it is the use of a solely future baseline that is "misleading" and "uninformative." Indeed, the DEIR's maps of aquatic resources and vegetation communities on the Centennial site appear to be deliberately misleading: both maps have a large blank area (characterized as 28.25 acres of the 56-acre site) described as "Area *Previously Disturbed* by DTSC clean-up project (Estimated)" *(Emphasis added)*. This description creates the false impression that these future conditions are in fact the current conditions.

This "future-only adjusted baseline" is used for five of the 13 environmental issues reviewed, including Biological Resources, without providing any substantial evidence to justify this choice. The premise of the adjusted baseline is that because the Centennial site "will" be cleaned up at some indeterminate time in the future, the environmental impacts of the mine should be measured as if the cleanup has already been completed.

As explained above, the premise underlying the "adjusted" baseline is unfounded for several reasons. First, the DTSC has not selected a specific cleanup plan, has never approved the proposed RAP, and the RAP may never be approved. Second, the DTSC MND review process is flawed and is based on a segmentation that is improper under CEQA. Third, as held in a 2021 California Court of Appeals case, applying two different types of environmental review (an MND and an EIR) to different portions of the same project violates CEQA. *Farmland Protection Alliance v. County of Yolo* (2021) 71 Cal. App 5th 300. The remedy is to start over and review all portions of the project using an EIR.

Based on this improper definition of project which excludes the Centennial cleanup, the DEIR and several of the supporting biological resources assessments and management plans flatly and repeatedly assert that the IMM will have "no impact on the wetlands" at the Centennial site, an assertion which is patently false.

**B. The DEIR's Use of an Adjusted Future Conditions Baseline for the Centennial Site Obfuscates the Project's Impacts on Plants and Habitats.**

**Grp 5-5**

Section 4.4.2 of the DEIR states that: "for the purposes of this biological resources analysis, the environmental baseline for the Centennial Industrial Site has been adjusted to be consistent with anticipated site conditions at the completion of the separate Centennial Industrial Site Clean-up Project. It is estimated that approximately half of the Centennial Industrial Site will consist of graded and revegetated areas under the post-remediation condition." (DEIR p. 4.4-2).

CEQA Guidelines make clear that "A lead agency may use projected future conditions (beyond the date of project operations) baseline as the sole baseline for analysis only if it demonstrates

with substantial evidence that use of existing conditions would be either misleading or without informative value to decision-makers and the public. Use of projected future conditions as the only baseline must be supported by reliable projections based on substantial evidence in the record." (14 C.C.R. § 15125(a)(2)).

There is no substantial evidence to support the use of a future baseline this case. The cleanup has not taken place, the wetlands are presently intact, and the intermittent and ephemeral streams still exist. Moreover, as noted above, the draft Remedial Action Plan for the Centennial site has not been approved, and no specific plan has been selected.

The DEIR adjusted baseline relies on "estimates" of the aquatic resources and vegetation communities that will exist on site once the cleanup is completed, yet the parameters of the estimates are vague:

"[T]he exact acreages of each aquatic resource type cannot be precisely established for the baseline condition given that the baseline has been adjusted to account for the planned remediation efforts that will be conducted under DTSC oversight pursuant to the RAP that has been prepared and publicly reviewed for DTSC approval. Final disturbance acreages to aquatic resources as a result of remediation activities may vary from current estimates. As a result, the disturbance acreages identified herein are conservatively estimated." (DEIR 4.4-10)

This statement asserts that using the adjusted baseline makes it impossible for the DEIR to provide specific or accurate estimates of amount of each aquatic resource type that will be impacted by the project.

In other words, because the RAP has not been approved, and because no specific cleanup plan has been chosen, it is unknown what remediation "efforts" will be undertaken, or what the effects of those "efforts" will be.

This means that the baseline fails to provide any way to accurately measure the resulting environmental impacts. Accordingly, the DEIR has chosen a future baseline that is purely hypothetical.

This lack of certainty undermines the purposes of CEQA. By relying on an undefined future baseline, the DEIR fails to properly analyze the project's potential impacts to wetlands and special status plant species on the Centennial site, among other environmental impacts. Indeed, it is the proposed future baseline, and not the existing conditions, that is misleading and "uninformative" to decision makers and the public.

The future environmental baseline also violates CEQA's intent and its requirement of public disclosure. "An EIR is an informational document which will inform public agency decision-makers and the public generally of the significant environmental effect of a project, identify possible ways to minimize the significant effects, and describe reasonable alternatives to the

project." (14 C.C.R. § 15121(a)). The public should be given a clear idea of the environmental impacts on the actual environmental setting, not conservative estimates that are subject to change because the DEIR failed at the outset to accurately describe the environmental setting.

This uncertainty is in stark contrast to DEIR Appendix F-1, "Aquatic Resources Delineation of Waters of the United States and State of California" for the Centennial Site, which clearly delineates 4.37 acres of mapped wetlands and .6 acres of streams, including intermittent and ephemeral streams, on the Centennial site. (pp. 5-1 to 5-4)

See also DEIR Appendix F-5, "Centennial Aquatic Resources Management Plan" ("ARMP"). As noted above in Section III, the plan notes that 4.54 acres of wetlands and streams "inside the area of disturbance for the IMM Project" will be impacted, but that the "impacts and associated mitigation" for these aquatic resources "will be incorporated into the DTSC voluntary cleanup project and is [sic] outside the scope of the IMM." Appendix F-5 p. 5-1.

The ARMP goes on to state that "After the environmental cleanup work at the Centennial ... Site is complete, ... engineered fill [will be trucked from the Brunswick ... Site to the Centennial Site." There would be a total surface area disturbance of approximately 44 acres, "including the previously disturbed area from the DTSC cleanup project..." The portion of the disturbance assigned by the DEIR to the IMM Project "would disturb approximately 0.033 acres to mapped streams."

The DEIR thus proposes mitigation only for this 33/100 of an acre (~1472 sq feet, about the size of a small house) of mapped streams, and no mitigation whatsoever for the 4.54 of wetlands and streams mapped in the Aquatic Resources Delineation.

The use of a future "adjusted baseline" together with the "piecemeal" project description obscures the actual impacts to wetlands and other biological resources on the Centennial Site. It also prevents any meaningful evaluation of those environmental impacts or appropriate mitigations for those impacts. These are all serious violations of CEQA that undermine and obstruct its purposes.

**C. The Botanical and Wetland Surveys and Management Plans Do Not Meet CEQA Standards**

**1. Botanical and Wetland Surveys Were Not Seasonally Appropriate to Identify Plants and Wetlands on the Project Site.**

**Grp 5-6**

Reconnaissance surveys for this project were done in December 2018, and protocol-level surveys were conducted in July and August 2019. The wetland surveys were done in December, July, 2019, and August 27, 2020. The late-summer surveys fall outside of the blooming periods for many of the special-status plants that have potential to occur on the project site, and at a time that many wetland features would not be evident. Because the surveys were deficient,

they may have failed to confirm special-status plants and wetland features that are in fact present on site. Any analysis, conclusions, or mitigation measures for impacts to special-status plants and to wetlands are inaccurate and not based on substantial evidence.

An independent peer review by Madrone Ecological Consulting found many deficiencies in the biological aquatic resources assessments and management plans.

These include failure to conduct appropriately timed surveys for special status plants at both the Centennial and Brunswick sites. The Madrone Peer Review noted that surveys were only conducted in July and Aug 2019. Botanical surveys were conducted for the Centennial Industrial Site on July 1, 10 and 14, 2019, and for the Brunswick Area, on July 1, 14, and August 16, 2019.

California Department of Fish and Wildlife (CDFW) "Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Sensitive Natural Communities" require that botanical field surveys be conducted in a manner that maximizes the likelihood of locating special status plants and sensitive natural communities that may be present. Surveys must be conducted at the times of year when plants will be both "evident" and "identifiable," usually during flowering season.

The Protocols also provide that:

*Surveys are to be spaced throughout the growing season to accurately determine what plants exist in the project area, which usually involves multiple visits to the project area in early, middle and late season.

*When special status plants are known to occur in the types of habitat present in a project area, reference sites are to be observed to determine if the special status plants are identifiable at the times of year the surveys take place.

*Additional botanical field surveys may be necessary [if], for example, ... surveys were not conducted at the appropriate time of year; were not conducted during a sufficient number of years to detect plants that are not evident and identifiable every year [e.g., fritillaries]; or if fire history or other conditions have changed since the last botanical survey was conducted.

*Because adverse conditions from yearly weather patterns may prevent botanical field surveyors from finding or accurately identifying some special status plats in a given year, all adverse conditions should be discussed in the survey report.

The Madrone Peer Review concluded that the field surveys for several potential special-status species were not conducted in accordance with the CDFW Special-Status Plant Survey Protocols in several respects:

A. "Surveys were not conducted during the identifiable season of all target species. Outside of the "identifiable season" plant species may no longer be visible ... may be less

evident (easily overlooked), and are often not possible to identify to a level necessary to determine rarity."

The only surveys were done in July and August 2019, which is later than the blooming season of several flowers. Citing data from the California Consortium of Herbaria, the Madrone review noted that Stebbins' morning glory, Butte County fritillary, and Cedar Crest popcornflower have never been documented as blooming as late as July or August, and thus they would not have been both evident and identifiable at the time the surveys were conducted. [ *"Stebbins' morning glory is almost always documented in May or early June, Butte County fritillary is almost always documented in March or April, and Cedar Crest popcorn flower has only been collected in April or May." Madrone Report p. 4.*]

The Madrone Review also identified Red Hills soaproot, finger rush, and dubious pea as plants typically identifiable earlier than July.

The Review concluded that "Surveys were not conducted during the identifiable season of all target species" and recommended that "full, protocol-level surveys for [six] plant species be conducted." It appears that no such additional surveys were conducted.

B. The Madrone Review also noted that "The CDFW survey protocol requires site visits for special-status plants with potential to occur on a project site ... [yet] Reference visits were conducted for only one of the target plant species. ... Without reference site visits, it is hard to know if the target plants were identifiable when the surveys were conducted." It appears that no additional reference site visits were conducted.

C. Citing CDFW Protocol requirements that surveys and plant lists be comprehensive, the Madrone Review identified a number of plant species that had been omitted from the pant list. In addition, the Review observed that no species from the genera Sidalcea and Fritillaria. The Review expressed concern regarding these omissions, because species of these two genera (Sidalcea and Fritillaria) appear on the list of special-status plants with potential to occur within the Study Area. The Review expressed concerns that the Biological Resources Reports failed to identify and document these genera, and recommend that an additional special-status plant survey be conducted during the blooming period for the special status species in these genera." Madrone Review p. 5. It appears that no additional special-status plant surveys for these species were conducted.

**Grp 5-7**

D. The Madrone Review noted that CDFW Protocols require that special-status plant surveys include a discussion of sensitive natural communities, and that the biological assessments did not include any discussion of sensitive natural communities. Madrone

recommended that sensitive natural communities be discussed." It appears that no discussion of sensitive natural communities was added to the biological resources assessments.

In addition to these observations of the Madrone review, a wildfire in August, 2021, burned substantial portions of the Centennial Site; this fire triggered the "changed conditions" provisions of the CDFW. Some of the special status plants present or potentially present on the Centennial site are fire adapted. Such adaptations include seeds that germinate after fire, or basal resprouting of burned plants. Biological surveys were required after the fire to locate new post-fire seedlings.

See *Effects of a firebreak on plants and wildlife at Pine Hill, a biodiversity hotspot*, J.M. Klip, M.R. Caldwell, D.R. Ayres, and V. Meyer California Fish and Wildlife, Fire Special Issue, pp. 58-81 (2020) (Pine Hill Flannelbush seeds are cued to germinate by fire's heat; over 1,100 Pine Hill Flannelbush seedlings were found within 13 months of 1983 experimental fire, with no additional seedlings sighted until 2020 when several piles of vegetation were burned a year earlier in 2019.)

**Grp 5-8**

See also Effects of Fire on the *Demography of Three Rare Chaparral Plants (Calystegia stebbinsii* [and two others]), Conference paper at Symposium of the Botanical Society of America (2009)(D.R. Ayres) (in plot that had no Calystegia stebbinsii [Stebbins' morning glory] before fire, C. stebbinsii germinated profusely the first spring after the fire, and began blooming heavily three years after fire).

Accordingly, a new survey is necessary to determine the effects of the fire on the existing Pine Hill Flannelbush and on seedbanks that may contain dormant C. stebbinsii seeds at the Centennial site. An additional survey needs to be done for post-fire seedlings of the protected rare C. stebbinsii. In addition, the Management Plan for the Pine Hill Flannelbush requires updating to determine which if any of the Pine Hill Flannelbush were killed or damaged by the fire; whether any resprouted, and whether there are new seedlings that need to be protected and incorporated into the management plan.

The DEIR does not indicate that any post-fire surveys have been done; early spring of 2022 would be the best time to initiate such surveys.

**2. Mitigation Measures Improperly Defer Plant Surveys**

Deferring surveys is improper under CEQA for numerous reasons. Deferring environmental assessment to a future date is contrary to the "policy of CEQA which requires environmental review at the earliest feasible stage in the planning process." *Sundstrom v. County of Mendocino*, 202 Cal.App.3d 296, 307 (Cal. Ct. App. 1988). "Environmental problems should be considered at a point in the planning process 'where genuine flexibility remains.' . . . A study conducted after approval of a project will inevitably have a diminished

**Grp 5-9**

influence on decision making. Even if the study is subject to administrative approval, it is analogous to the sort of post hoc rationalization of agency actions that has been repeatedly condemned in decisions construing CEQA." *Id.* (internal quotations and citations omitted).

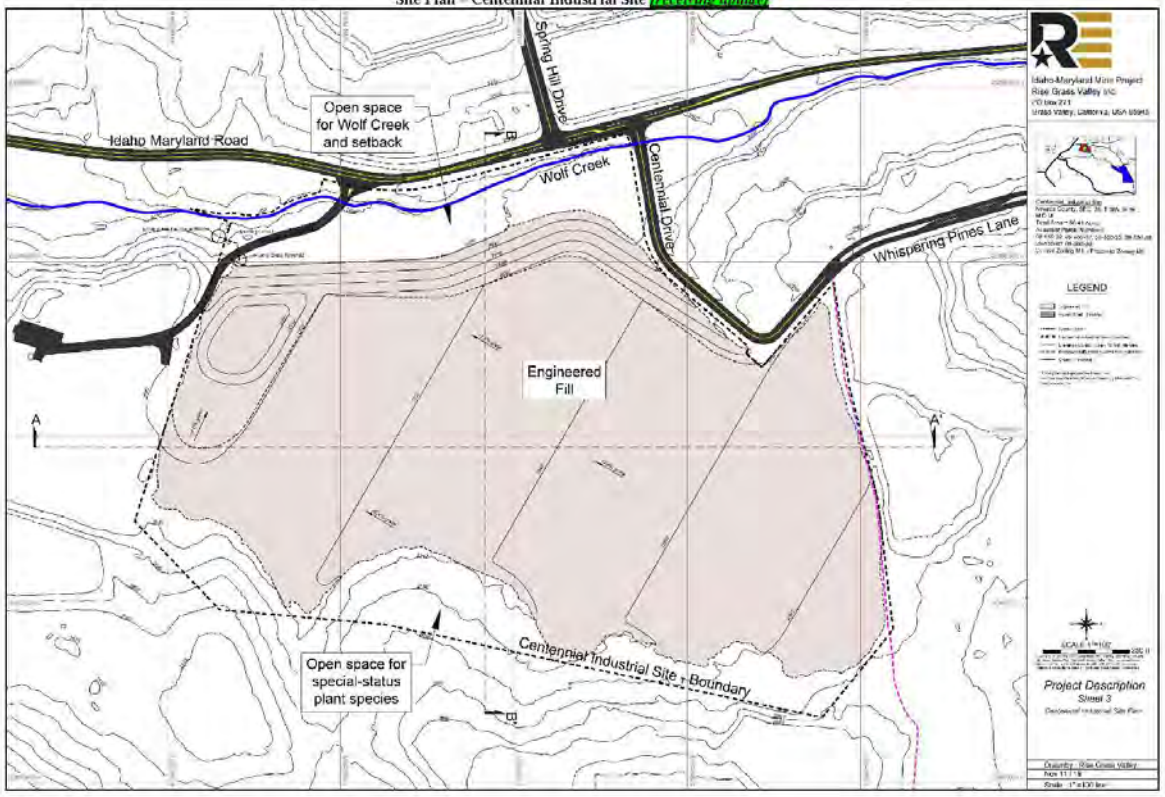
CEQA also gives the public the right to review projects before they are approved and provide public comment. The public is entitled to be informed of the results of plant surveys and how the project will impact plants and vegetation present on the project site. Delaying surveys until some vague, undefined time in the future after the project has been approved is contrary to these principles. Finally, delaying surveys until immediately prior to construction can make avoidance of special-status plants impracticable. If species are discovered during the survey that were not accounted for in the project design, last minute changes to project design are often prohibitively expensive, or impossible altogether.

The DEIR should not rely on preconstruction surveys to make up for the late-season or botanical surveys conducted in 2019 or for the lack of post-fire surveys in 2022.

**Conclusion**

**Grp 5-10**

For the reasons described above, we respectfully request that the DEIR be redone, and that it include a review of the entire IMM project and cleanup, so that a full and accurate assessment of the true environmental impacts of this project can be completed and re-issued for public review.



Sincerely,

Isabella Langone

## GROUP LETTER 5: JEANNE WILSON, CALIFORNIA NATIVE PLANT SOCIETY – REDBUD CHAPTER

### Response to Comment Grp 5-1
Please see DEIR section 1.3 and Master Response 4 - Clean-Up Project is a Separate Project Under CEQA. Please also see Response to Comment Grp 20-8.

### Response to Comment Grp 5-2
Please see DEIR section 1.3 and Master Response 4 - Clean-Up Project is a Separate Project Under CEQA. Please also see Response to Comment Grp 20-8.

### Response to Comment Grp 5-3
Please see Master Response 4 - Clean-Up Project is a Separate Project Under CEQA, and DEIR Section 1.3 regarding use of an adjusted environmental baseline at the Centennial property given the separate Centennial M-1 Clean-Up project under review by DTSC.

Regarding the commenter's position the technical studies are inadequate because of the timing of biological surveys, please see Master Response 30 - Technical Study Adequacy, Master Response 31 - Rare Plants, and Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog.

### Response to Comment Grp 5-4
Please see Master Response 4 - Clean-Up Project is a Separate Project Under CEQA, and DEIR Section 1.3 regarding use of an adjusted environmental baseline at the Centennial property given the separate Centennial M-1 Clean-Up project under review by DTSC. The Centennial Site cannot be used as part of the project unless and until the DTSC cleanup project has already been completed. Thus, the baseline used in the DEIR is appropriate for the Centennial Site and related impacts. Please also see Response to Comment Grp 20-8.

### Response to Comment Grp 5-5
Please see DEIR Section 1.3 and Master Response 4 - Clean-Up Project is a Separate Project Under CEQA. Please also see Response to Comment Grp 20-8. As noted in D EIR Section 4.4.2, the estimates included in the DEIR are conservative and overinclusive of potential impacts areas in the event minor changes to the separate DTSC clean-up project occur.

### Response to Comment Grp 5-6
The commenter asserts that botanical and wetland surveys were not adequate due to timing issues. Please see Master Response 30 - Technical Study Adequacy, Master Response 31 - Rare Plants, and Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog. As noted by the commenter, extensive peer review of the technical studies were conducted by the County's independent consultant. Following review and comment, technical studies were revised and resubmitted to the County in consideration of the County consultant's comments. The County accepted the revised technical studies and used the information to perform their biological impact analysis.

### Response to Comment Grp 5-7
Please see Response to Comment Grp 5-6 above.

### Response to Comment Grp 5-8
Please see Master Response 31 - Rare Plants, and Appendix G to this Final EIR, which includes the results of a rare plant survey conducted after the wildfire cited by the commenter. Mitigation

Measures 4.4-1(a) and 4.4.1 (b) require the applicant to implement the Centennial Pine Hill Flannelbush Habitat Management Plan, obtain an ITP from CDFW for impacts to Pine Hill flannelbush, complete another set of protocol-level special status plant surveys, and consult with Nevada County Planning Department, as well as CDFW and/or USFWS if the plant is state- or federally-listed. Therefore, no additional mitigation is required to reduce potential impacts to special status plants to a less than significant level.

## Response to Comment Grp 5-9

This comment is conclusory in nature, stating that the DEIR defers mitigation and does not sufficiently identify performance standards. The comment does not identify any specific mitigation measures that are deficient. In the case *Center for Biological Diversity v. California Department of Conservation, etc*. (2019), the court explains that "[g]enerally, it is improper to defer the formulation of mitigation measures…However, an exception to this general rule applies when the agency has committed itself to specific performance criteria for evaluating the efficacy of the measures to be implemented in the future, and the future mitigation measures are formulated and operational before the project activity that they regulate begins." (36 Cal.App.5th 210, 239.) The court determined both conditions were met and upheld the deferred mitigation measures. Similarly, the mitigation measures presented in the DEIR require compliance with specific performance standards and regulatory requirements, and also require implementation prior to project activities begin.

The DEIR included rare plant surveys, conducted by experts in the field and with knowledge of the region, as Appendices F.6 and F.11. These technical studies were peer reviewed by the County's independent consultant and, once those comments were addressed, the County utilized this information to prepare their impact analysis. As concluded in the DEIR, impacts to special status plants are potentially significant and mitigation measures were provided. The mitigation measures require conducting preconstruction surveys prior to onsite surface disturbance to ensure no new special status plant species would be impacted by project construction. The DEIR clearly identifies potential special status plant species that may be impacted by the project. The mitigation measure clearly establishes performance standards and timing for when preconstruction surveys shall be conducted and what should occur based on the results of those surveys. As a result, the DEIR clearly identifies the potential impacts to special status plants and provides enforceable mitigation measures. In addition, please see Master Response 31 - Rare Plants and Appendix G to this Final EIR, which includes the results of a rare plant survey conducted after the wildfire and release of the DEIR. Mitigation Measures 4.4-1(a) and 4.4.1 (b) require the applicant to implement the Centennial Pine Hill Flannelbush Habitat Management Plan and complete focused special status plant surveys. Therefore, no additional mitigation is required to reduce potential impacts to special status plants to a less than significant level.

## Response to Comment Grp 5-10

The commenter requests that the DEIR be revised and recirculated with the DTSC cleanup project included in the Project Description. The commenter's specific comments are addressed in Responses to Comments Grp 5-1 to Grp 5-9. The County has concluded that the DEIR is adequate, and recirculation is not required.

RE: The County has NOT made a determination on the Idaho-Maryland Mine

Dear Supervisors:

**Grp 6-1** As you may be aware, Idaho-Maryland Mine owner Rise Gold Corp has sent out yet another mailer to Nevada County residents, this time claiming that "Nevada County **has just completed** the most thorough environmental study in its history," along with numerous unresolved claims about the project. The mailer includes a form for supporters to mail in to Rise Gold.

We want to bring your attention to another letter that was sent to well owners in the mine area. (Copy included)

**Grp 6-2** The letter states: "**The County has determined** that no domestic water wells will be drained by mine dewatering," that "**The County has determined**, using a safety factor of 100%, that several wells...could be impacted...to a maximum of 10 feet," and "**The County has determined** that there is no threat to water quality to domestic water wells from the Idaho-Maryland Mine Project."

**Grp 6-3** We feel that it would serve the public interest for the County to issue a clarifying statement regarding the status of the Draft EIR and the status of determinations by the County.

Thank you.
Sincerely,
Ralph

Rise Grass Valley Inc.
333 Crown Pt Circle, Ste 215
Grass Valley, CA 95945 USA

February 11th, 2022

[redacted]
Grass Valley, CA 95945

Mr. [redacted],

The Idaho-Maryland Mine Project proposes reopening the Idaho-Maryland underground mine with facilities constructed on the Brunswick Industrial site located south-west of the Brunswick Road and E. Bennett Road intersection. Nevada County has recently issued (January 4th, 2022) a Draft Environmental Impact Report (the "DEIR") for the Idaho-Maryland Mine Project. Rise has reviewed this document in detail over the last month and we are reaching out to you to provide further information on our project.

Rise Grass Valley Inc. (Rise) is the owner of the mineral rights, starting 200 feet and deeper beneath your surface property including all necessary and convenient rights to extract them, excepting the right of entry to the surface land. To access its mineral estate, Rise must first dewater the underground mine, and because your property is on a well, extensive research and modeling by certified, licensed hydrogeologists took place to assure us, the County and you how your well might be affected. While Rise does own the mineral rights deeper than 200 feet below the surface, Rise respects your surface property rights and is committed to being a good neighbor and community member. Out of an abundance of caution, Rise plans to provide you the option to connect to NID water at Rise's expense.

The hydrogeologic analysis was peer-reviewed by an independent California-licensed hydrogeologist. The County has determined that no domestic water wells will be drained by mine dewatering. The County has determined, using a safety factor of 100%, that several wells in the East Bennet Road area could be impacted by a reduction in the water column of wells ranging to a maximum of 10 feet. It should be noted that the water level in the existing mine workings is already approximately 100 feet below the depth of groundwater in your area, which illustrates that the mine is not hydrologically connected by significant fractures to the shallower groundwater well due to the impervious nature of the surrounding rock. Nevertheless, to ensure that you have 100% confidence in an uninterrupted access to water, Rise has committed to construct, at its own cost, an extension of the Nevada Irrigation District (NID) potable water system along E. Bennett Road which could service your property if you choose. This construction and connection would take place before any mine dewatering commences. Thus, you will have the option of either connecting to NID water, at Rise's cost, and/or continuing to use your domestic well. The County has determined that there is no threat to water quality to domestic water wells from the Idaho-Maryland Mine Project. Water does not flow upward from the mine

workings to feed your well, and as the water in the mine workings is removed, that would continue to be the case.

If you decide to utilize NID potable water, Rise will fund the connection to your property. The value per property owner, including capacity charges, is estimated at approximately $85,000. Rise would also pay for your ongoing water charges as long as you own your property. A high-quality water supply from NID would alleviate your ongoing treatment and monitoring of your current well. In addition, this water supply is reliable and not interrupted during our area's increasingly frequent power outages.

If requested by the landowner at the time of NID connection and service to their properties, Rise will pay to close property owners' wells using certified well drillers and under Nevada County regulations.

If the Nevada Board of Supervisors approves the project, we will proceed with the detailed design of the potable water line. We will consult with you about your preference in meter location and desire to connect to the NID potable water system.

The Idaho-Maryland Mine Project also has direct benefits to fire protection for your property. The extension of the water pipeline along E. Bennett Road will allow for installing of fire hydrants and allow firefighters to respond to fires in your area much more efficiently. Rise has also agreed to provide Ophir Hill Fire Protection District with a new fire engine and additional firefighters which will significantly enhance their ability to provide excellent service in your area.

Your property is over 1/2 of a mile away from the Brunswick site, and it would not be impacted by noise during operations. Rise will not route truck traffic along E. Bennett Road adjacent to your property. Technical analysis, performed by an expert PhD, shows that the anticipated vibrations from drilling and blasting underground are negligible, and in almost all situations, drilling and blasting will be unnoticeable and undetectable.

Rise recently engaged RCLCO Real Estate Consulting, a highly respected firm, on the potential effect of the Idaho-Maryland Mine Project on local real estate values in the local area. RCLCO found no negative impact on home prices based upon case studies or recently opened mines. However, due to demand created by employment, homes sold closer to a mine actually achieve higher pricing than those sold farther away. We believe the extension of NID water service will increase the value of your property, as will the economic impact of the 300+ high-paying jobs and approximately 300 indirect jobs that the project will create.

You can learn more about the Idaho-Maryland Mine Project at www.risegrassvalley.com and our company at www.risegoldcorp.com. If you are interested in more information, have any concerns, or wish to support our project please contact me and I would be pleased to arrange a

meeting in our Grass Valley office or at the Brunswick site. If you would like to meet in person or speak further about our project and the proposed NID water service, please contact me by phone or email as below.

Sincerely,

Ben Mossman

## GROUP LETTER 6: RALPH SILBERSTEIN, COMMUNITY ENVIRONMENTAL ADVOCATES FOUNDATION

### Response to Comment Grp 6-1

The comment is noted. The commenter is referred to Master Response 1 - Non-EIR/Administrative Issues.

### Response to Comment Grp 6-2

The commenter summarizes the contents of a mailer provided by the applicant, which is provided as an attachment for the County to review. The comment does not address the adequacy of the DEIR. Comment noted.

### Response to Comment Grp 6-3

The comment is noted but does not address the adequacy of the DEIR. Please also see Master Response 15 – Adequacy of Groundwater Monitoring Wells.

**Group Letter 7**

Comments on the Draft Environmental Impact Report for the Idaho-Maryland Mine Project

To All Concerned:

**Grp 7-1**

This letter is written on behalf of Community Environmental Advocates Foundation, The Sierra Fund, South Yuba River Citizens League, Wolf Creek Community Alliance, the state office and the Redbud Chapter of the California Native Plant Society, Sierra Foothills Audubon Society, Sierra Nevada Group Sierra Club, Friends of Bear River, Nevada County Climate Action Now, Brunswick Manor HOA, San Juan Ridge Taxpayers Association, Earth Justice Ministries, Elders Action Network, Patagonia, Friends of Banner Mountain, the Wells Coalition, Sierra Streams Institute, Brunswick Pines Road Association, Wawona Madrono Homeowners Association, and members of the Nevada County community at large who have identified many issues of concern regarding the potential reopening of the Idaho-Maryland Mine (Mine, Mine Project, or Project) Grass Valley.

As a coalition of community and environmental organizations in Nevada County, we appreciate the opportunity to provide public comment on the Draft Environmental Impact Report (DEIR) released by Nevada County for public review on January 4, 2022, addressing the environmental impacts of re-opening and operating the Mine for the next 80 years.

We are concerned about the long-lasting environmental impacts that the Mine Project would cause and the inadequacy of the environmental analysis of the DEIR. A number of key points are provided here. More detailed and complete comments from individuals and organizations are being submitted separately.

Note documents cited and submitted under separate cover:

- Baseline Environmental Consultant Report, Feb 15, 2022 (Baseline).
- Salter Report, March 9, 2022 (Salter).
- Comments on the Idaho-Maryland Draft EIR - 16Mar22, Center for Science in Public Participation (CSP2).

PROJECT DESCRIPTION

1 The DEIR does not adequately define the Mine Project to include the Centennial site and accordingly, fails to identify all potential impacts.

Grp 7-2

The DEIR fails to adequately address impacts associated with the Centennial Industrial Site (Centennial). This site is the location of hazardous waste left over from past Idaho Maryland Mine operations. The DEIR assumes that the Centennial site will be cleaned up before the use of the site for deposition of new mine waste. Yet the significant work which is needed to accomplish this clean-up is not disclosed nor evaluated in the DEIR. Rather, the DEIR assumes that the clean-up has already been accomplished, and uses the post clean-up conditions as the baseline for some of its environmental impact assessments.

The DEIR does not describe the current physical conditions of the Centennial site or include the necessary clean up of the existing contamination at that site as part of the Project because it assumes that Centennial will be cleaned up prior to the start of construction. As discussed above, the clean up for Centennial has not been approved by Department of Toxic Substances Control (DTSC) and it is unclear when DTSC might approve the clean up. Consequently, it cannot be excluded from this DEIR. As a result, any assumptions about baseline conditions for purposes of assessing impacts to the Mine Project are speculative at best, and at worst, significantly underestimate the actual impacts of the Project.

The current conditions of the Centennial site must be used as the DEIR baseline in order to meet the CEQA requirements for a full analysis of the impacts of the Mine Project. Moreover, the Centennial clean up should be included as part of the Project to address the whole of the action under CEQA. In order to accurately assess impacts, the existing conditions, or baseline, of the Project must be the current state of the Centennial site, not a speculative future condition.

2 Construction time estimates are inadequate and affect noise, traffic, air, and other impact areas.

Grp 7-3

Construction time estimates in the DEIR are contradictory and inadequate. For example, the DEIR states in several instances that the Project is estimated to have a twelve month construction phase, but also states that the construction of the water treatment facility alone would take eighteen months.

Furthermore, neither of these estimates - twelve or eighteen months - is sufficient to capture all phases of construction. As just one example, the applicant would have to complete significant grading and underground development before initiating the eighteen month construction of the water treatment facility. Similarly, the water treatment facility would have to be completed before dewatering of the mine could begin. Dewatering is a six month process. After dewatering has been completed, the new shaft for ventilation and emergency access would have to be constructed to the 1000' depth by working upwards from below. Then, before beginning any actual new mining, the tunnels would need to be restored sufficiently to allow for construction of the underground rock crushing facility. All of these activities must happen sequentially, not in parallel. Therefore, a more reasonable estimate of construction length for the Project would be four to six years, clearly resulting in significantly different annual and cumulative impacts than the ones identified in the DEIR.

**Grp 7-4**

The DEIR should be revised to provide an accurate description of each construction project, including its intended duration. This revised description must also include the sequencing of construction projects. Until this information is provided, the DEIR preparers will be unable to properly assess the annual and cumulative impacts on air, noise, traffic, aesthetics, and other resource areas.

3 The DEIR has not demonstrated that mine waste disposal by off site sales would be viable.

The DEIR indicates that the applicant (Rise) plans to sell waste rock on the open market if it is still being produced after the two proposed waste rock piles reach capacity (DEIR Project Description). The Regional Water Board has jurisdiction over the disposal location requirements for mine waste rock. Although the DEIR does not disclose this, the concept of selling waste rock is an unrealistic and infeasible proposal unless the Water Board has determined that such discharges would not pose a threat to water quality. Accordingly, the Project should not rely on this concept and the DEIR should identify all impacts associated with alternative disposal methods.

**Grp 7-5**

Even if the mine waste can be sold, the market for aggregates varies significantly by season. During rainy seasons, it may be necessary to stockpile the aggregate onsite, but there are no provisions for onsite storage in the DEIR or an assessment of impacts related to such storage. As reported by the Center for Science in Public Participation (CSP2), dispersing waste rock and other mine waste over large areas without containment often results in contamination (e.g., Calcine mercury mine tailings used for road construction in San Luis Obispo County). (CSP2)

The absence of provisions for temporary waste rock storage (and the associated analysis of its impact) creates strict operational constraints and potential impacts on all phases of processing have not been addressed in the DEIR. The DEIR should be revised to include an analysis of these impacts.

4 Mine waste and ore processing stockpiling: proposed processes may not be viable due to the necessary safeguard controls for asbestos.

**Grp 7-6**

(See "ASUR Plan Analysis.pdf", attached as a reference to this letter. Portions of that document are summarized here.)

The plan described in the DEIR for managing asbestos-laden mined materials is inadequate. Asbestos is likely to be released during underground blasting, crushing, and ore processing. It also is released during material handling, on-road transport, placement grading and compaction. The DEIR states that the Asbestos Management Plan would ensure that average mined material and engineered fill contains less than 0.01% asbestos. (DEIR 3-20) Testing the asbestos content, however, does not control the amount of asbestos in the actual material mined. To control the average amount of asbestos in output materials (and to avoid significant impacts related to asbestos exposure), the DEIR must ensure that asbestos levels do not exceed this threshold. Currently, the DEIR does not include any evidence that asbestos levels will not exceed this threshold.

The testing process may require up to two weeks before the results are known, yet the Project calls for daily mining activity to continue during this time. This daily mined material would have to be stockpiled while awaiting the test results, which could expose workers to dangerous levels of asbestos. The DEIR does not disclose this fact nor does it analyze the associated impacts.

In addition, if the running average of asbestos in the daily mined material exceeds the required threshold, batches containing higher asbestos levels would have to be stockpiled in order to be later mixed with batches having lower asbestos levels. The DEIR does not disclose this fact nor does it analyze the associated impacts.

**Grp 7-7**

The mineral processing described in the DEIR does not address the need for stockpiling materials or address the likely impacts of such efforts. The Asbestos Management Plan provided in the revised DEIR must detail all of the steps necessary to carry out the correct management of this hazardous waste, including the location and organization of stockpiled materials, and adequate safeguards to avoid fugitive dust emissions and potentially hazardous conditions.

HAZARDS AND HAZARDOUS MATERIALS

5 The DEIR inadequately describes potentially hazardous waste rock and mine tailings management.

As pointed out by Baseline Engineering Consultants (Baseline), the legacy contamination from prior mining indicates that the types of rock historically mined at the site contain heavy metals and, when excavated, these waste rock and mine tailings have been found to contain contaminants that pose a potential risk to people and the environment.

**Grp 7-8**

*"Neither the DEIR Project Description nor the Hazards and Hazardous Materials section adequately describes how future waste rock and mine tailings generated by the proposed project would be managed to ensure that they do not pose a health hazard to people or the environment (as the placement of similar waste materials from the same mine did in the past)" (Baseline).*
The revised DEIR must provide adequate information about the potential risks of the waste rock tailings and all potential impacts.

WATER QUALITY

6 Drill core testing for water quality impacts is inadequate.

Given the size and scope of the proposed Project, there was an insufficient quantity of drill core rock analyzed to determine the mine's true impact on water quality.

By way of illustration, between 2017 and 2019, the applicant drilled for, and extracted, a total of 67,500 feet of rock core. But of these 67,500 feet of drill core, only 0.68% were submitted for analysis. And of the few samples that were submitted for analyses, a dearth of information is provided regarding the sample materials' true weight, volume, particle size, and sampling technique. Nor are the drill logs for these core samples available for review, so the actual dates, precise locations, drift angles, widths, final depths, etc. are unknown. Several times the DEIR refers the reader to a "separate report" which will explain some of these omissions, but no such report is found in the document or its appendices.

**Grp 7-9**

In addition to the limited sample size and the inadequate sampling details, four different labs were employed to carry out the analyses of the submitted samples, but the samples did not have a proper chain of custodies (COC) processes. The COC is a process that tracks the movement of samples through their collection, safeguarding, and analysis lifecycle between the mine applicant and the labs, but the COCs do not reflect the written account found in the DEIR.

The revised DEIR must provide an explanation for the discrepancies in the chains of custodies for the samples submitted to labs and provide evidence that the samples are scientifically reliable.

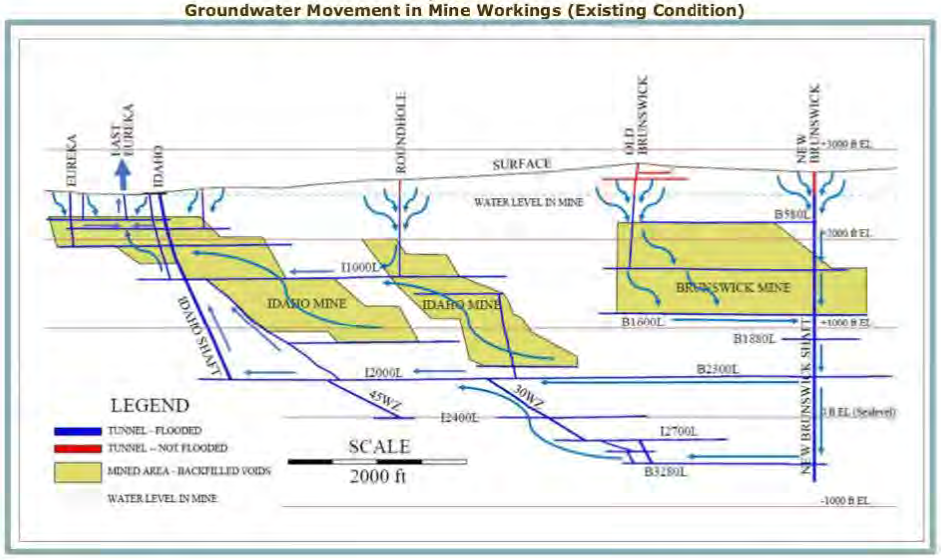
This insufficient and unreliable data affects the accuracy of any analysis based on this data, such as an analysis of the metal leachate content of rock. Since metal leachate from mine rock affects water quality, analyzing metal leachate is one of the key concerns regarding the rock tailings produced by the Project. The limited amount of core material sampled and the imprecise manner in which the details of the core samples are reported makes the metal leachate analysis unreliable and leads the DEIR to underestimate potential impacts.

**Grp 7-10**

The revised DEIR should include a full set of data and drill logs that can be reliably analyzed by the public.

**Grp 7-11**

7 Assessments of the current mine water chemistry are inadequate.



The Hydrology Report (DEIR Appendix K.2, Table 4-10, p120) uses discharge screening limits and data from the New Brunswick shaft to define water treatment criteria. However, a more accurate sampling of mine water would be from the drains located along Wolf Creek rather than from the New Brunswick shaft, as described in the analysis of mine water flow (see DEIR Figure 4.8-7), which shows water entering the New Brunswick shaft then flowing downward through the

**Grp 7-12**

extant mineworks to exit the drains at Wolf Creek (Eureka drain, East Eureka drain, etc). Only a few samples taken from the drains were reported, but these samples are much more representative of the mine water chemistry and indicate higher levels of Iron, Manganese, Arsenic, Aluminum, and Zinc than the New Brunswick shaft samples (DEIR K.2 Tables 3-6).

In order to get an accurate assessment of the contaminants flowing out of the mine under varying conditions, regular testing must be conducted over time at the Mine drains. The testing must also be conducted seasonally during differing rates of outflow. Moreover, in order to provide the public with a conservative estimate of potential impacts, the DEIR should use the results from the drain samples rather than the New Brunswick shaft, which would show potential water quality impacts from higher level of metals, arsenic and zinc.

**Figure 4.8-7**
**Groundwater Movement in Mine Workings (Existing Condition)**

**8 The hydrology study incorrectly assesses the potential for long term acid mine type drainage.**

**Grp 7-13**

The Empire Mine, adjacent to the Idaho-Maryland Mine, provides clear evidence of the potential for contaminants that could be discharged from the Mine and from tailings and mine waste intended to be deposited on the surface or back within the Mine as backfill. Mine water discharged from the Empire Mine has excessive levels of arsenic, iron, and manganese.

The EMKO hydrology study used in the DEIR dismisses the potential for acid drainage which could affect water quality in Wolf Creek. Instead, the DEIR claims "Any acid generated during the oxidation would be quickly neutralized by the carbonate minerals in the host rock" and cites neutral or high (non acid) pH values. (DEIR 4.8-49, 50) However, the short term method used by EMKO is not a reliable method for predicting the long term potential for contaminants to be discharged from mine waste. Results would be more reliable using long term tests, on the order of months rather than hours or days.

The waste rock's potential to produce poor quality effluent should be thoroughly characterized using appropriate tests to the satisfaction of the Water Board (e.g., ASTM D 5744) over a sufficient period, also to the satisfaction of the Water Board (e.g., 40 weeks).

Accordingly, more extensive testing of mine waste rock and tailings must be conducted to assess the potential for contaminant leaching from mine waste. Long term dynamic testing must be conducted to accurately identify potential impacts to water quality. Due to variations in geology as mining progresses, repeated testing of the mine waste must be done.

**Grp 7-14**

The revised DEIR must specify how long-term monitoring of acid mine type drainage would be accomplished and identify mitigation measures capable of ensuring that any unanticipated contaminants do not adversely affect water quality. Without providing such testing and identifying feasible and effective mitigation measures, the impact must be identified as significant and unavoidable.

9 It is not adequate to defer analysis of mine waste, a potential hazard, to some future date without providing substantial evidence that the proposed actions will not result in environmental impacts.

**Grp 7-15**

The mine waste has not been adequately tested and one must conservatively conclude that it has a high potential for causing water quality impacts, given that similar local historic mining activities resulted in the detrimental environmental impacts that persist today. The DEIR fails to conduct the necessary impact analysis. Instead the document asserts that impacts will be remedied by obtaining an expedited General Order permit from the Water Board (DEIR section 4.8 page 50). As Baseline points out, this process is insufficient:

*"It is not adequate to state that the project will get permits without providing substantial evidence that the proposed action will not result in environmental impacts, particularly when very similar historic actions have been demonstrated to result in environmental impacts that have persisted for decades."* (Baseline)

The revised DEIR must provide a valid and reliable analysis of the mine's waste products and identify specific and achievable mitigation measures to assure these water quality impacts are reduced to less than significant levels. Alternatively the revised DEIR must identify such impacts as significant and unavoidable.

HAZARDS - AIR QUALITY

10 The DEIR provides no evidence that the project's long-term NOx, ROG, and PM10 emissions will be mitigated to a less-than-significant level.

**Grp 7-16**

The DEIR fails to adequately mitigate the Project's air quality impacts. It relies on a bare minimum of mitigation measures recommended by the Northern Sierra Air Quality Management District (NSAQMD) to address air quality impacts, and these measures only address emissions during a one year period of construction. As we explain above, construction will certainly last longer than one year. In addition, the mitigation measures do not address the long-term emissions that will result from 80-years of mining operations associated with the Project. As a result, there is no evidence that the Project's long term emissions have been mitigated to a less-than-significant level, as concluded by Baseline Engineering Consultants (Baseline).

The revised DEIR must identify feasible and effective mitigation measures that address emissions from 80-years of mining to ensure that emissions are kept at less-than-significant levels. Otherwise, the EIR must identify these long term impacts as significant and unavoidable.

11 The DEIR Health Risk Assessment uses invalid meteorological data to characterize emissions.

**Grp 7-17**

Toxic Air Contaminants (TAC) are toxins which may cause or contribute to an increase in death or serious illness from cancer and other acute or long-term diseases. (See Health Risk Assessment Critique (HRA Critique), attached as a reference to this letter.) TACs may cause health damage even at extremely low levels, and are generated by, among other sources, vehicles, off-road equipment, blasting emissions, and fugitive dust. TAC ingredients include particulate matter from diesel emissions, asbestos dust, silica dust, heavy metals, ammonium nitrate fuel oil, hexavalent chromium, and radon – all of which would be produced by mining activity, and which can become airborne, traveling on wind currents toward population centers around Nevada County.

The data used for the Health Risk Assessment model in the DEIR that relies on meteorologic information about the quality, quantity, speed, and direction of travel of air toxins is not appropriate for the Grass Valley area. The DEIR model relies on data from the Blue Canyon site, an area with a significantly different meteorological profile than that of Grass Valley. Blue Canyon, located on Highway 80, bears little meteorologic resemblance to Grass Valley: it deviates from Grass Valley in elevation, temperature, rainfall, snowfall, wind speed, and wind direction. Using Blue Canyon's meteorologic data does not correlate with Grass Valley meteorologic data under most circumstances, and makes any TAC statistic derived from the model unreliable.

The DEIR's Health Risk Assessment must be revised using meteorological data applicable to Grass Valley in order to accurately assess the potential health impacts of the mine's toxic air.

12 Drill core testing for airborne contaminants is inadequate.

**Grp 7-18**

As documented in "Sampling Procedures" (Sampling) (attached as a reference to this letter), TACs silica and asbestos are insufficiently described in the DEIR. Even though several hundred tons of rock would be mined and surface-stored each day, none of the core samples taken from the exploratory drill cores were tested for the contaminant silica. It also appears that when the original core samples were taken, drilling was stopped when serpentinite, an asbestos bearing rock, was encountered and, since drill logs are not available for review, the depth and width of the asbestos-containing serpentinite deposits encountered cannot be determined.

The rock types identified in the mineralized zone contain substantial amounts of silica (silicon dioxide, quartz), and the tailings would contain fine particles of respirable crystalline silica, a TAC. The laboratory that the applicant used for all metals analyses, ACZ Laboratories, is certified to perform both silica and silicon dioxide tests yet not a single sample was analyzed for these parameters (Sampling).

The revised DEIR should provide a full set of data about the samples analyzed for silica and asbestos. To the extent this data set fails to analyze silica and asbestos, further analysis and revisions of the DEIR are required to adequately identify impacts.

13 The management of fugitive dust after it leaves the mining facilities is inadequate.

In 1986, asbestos was identified by the California Air Resources Board (CARB) as a TAC. CARB also determined that there is not enough scientific evidence to identify an asbestos threshold level below which no significant adverse health effects are anticipated (17 CCR 93000, Implementation Guidance Document 2017, CARB pg 1), (HRACritique),

**Grp 7-19**

As a TAC, asbestos, as well as respirable crystalline silica, fall under the non-criteria air pollutant category because they lack an identified safe "threshold level below which no significant adverse health effects are anticipated." There are no established limits for monitoring emissions of non-criteria air pollutants, silica and asbestos, into the ambient environment. The Health Risk Assessment is based on 30 years of exposure, so the cumulative effects from 80 years have not been addressed. Both silica and asbestos are inert substances not subject to environmental degradation that will have potential impacts beyond the 80-year project permit. (HRACritique)

The revised DEIR should establish asbestos mitigation protocols and robust monitoring systems of waste rock during transport and disposal to ensure the protection of workers and the public from the adverse health effects associated with the TACs, asbestos, and respirable crystalline silica. Without identifying clear and achievable mitigation measures, the DEIR must identify this as a significant and unavoidable impact.

HYDROLOGY AND WATER QUALITY

14 The proposed project would intentionally affect local groundwater resources.

The proposed Project would significantly affect local groundwater resources by dewatering the mine, lowering groundwater levels. The dewatered groundwater resources would be converted to surface water that is discharged into existing creek channels and quickly conveyed out of the area. The applicant's consultants have prepared a numerical groundwater model to attempt to predict how this proposed long term dewatering effort would affect overlying and surrounding groundwater levels.

**Grp 7-20**

An incorrect assumption was made in the groundwater model used to predict dewatering impacts, which led the DEIR to significantly underestimate groundwater drawdown, both in magnitude and areal extent. The groundwater model was calibrated based on pumping rates from the historical Idaho Brunswick Mine and only one water level measurement collected from the flooded (i.e., inactive) Union Hill shaft in 1956. Using only one water level measurement from 64 years ago to calibrate a complex bedrock aquifer system over a large region is inappropriate and introduces a significant amount of uncertainty to the model. (Baseline)

The revised DEIR must rely on a corrected groundwater model in order to accurately predict the extent of the well drawdown caused by the predicted 80 years of mine-dewatering and dewatered maintenance. Based on existing reports, the Project is likely to impact significantly more wells than the number of wells identified in the DEIR.(see "Safeguards for Well Owners and the Idaho-Maryland Mine", CEA Foundation) This is a significant impact that will affect hundreds of Grass Valley residents and must be addressed in a revised DEIR.

15 The basic constructs of the DEIR's groundwater model have significant errors and omissions making them unreliable.

The basic data needed to build a valid groundwater hydrological model are missing. The document "Review of the Idaho-Maryland Mine DEIR Groundwater Model" (Model Review) by Silberstein examines deficiencies in the model, as summarized here.

**Grp 7-21**

The mine water drains from several locations along Wolf Creek near Centennial Drive, and the DEIR provides only rough approximations of the mine water outflow rates from these areas. What's more, these outflow data are contradicted by more reliable records from previous studies which indicate ten times more outflow than the amount the DEIR discloses. (Model Review) Similarly, mine water inflow analysis is based on sparse mine water level data from the New Brunswick shaft. Only 12 water level measurements were taken at random times of the year between 2003-2007, and just 3 measurements in 2018-19). In addition, the utility of these measurements is incorrectly interpreted. The water level reaches a limit when it exceeds the level of the drains from which the mine water flows and doesn't reflect what could be substantial

**Grp 7-22**

inflow. Without a measurement of the outflow, the amount of inflow cannot be determined by the water level in the New Brunswick shaft. Essentially, no water balance assessment is provided.

**Grp 7-23** Furthermore, data from private wells within the area is old and limited to just a few years. No usage data is provided, so seasonal variations in water levels are of limited use.

**Grp 7-24** Critical data such as reduction in groundwater recharge from precipitation are also incorrectly calculated, failing to include the 75 acres of low-permeable mine waste to be dumped on the two sites.

**Grp 7-25** Moreover, the groundwater model does not include the new access shaft, which would create a local area of groundwater drawdown. In fact, it appears that numerous existing mine features that are within a few hundred feet of the surface were also not evaluated in the ground water model. These mine features would contribute to the downward transmission of ground water from the near surface fractured rock areas.

These are all elements that are critical for constructing a reliable groundwater model to identify dewatering impacts.

**Grp 7-26** In addition, there are three major faults and numerous minor faults in the mineral rights area. These impact the transmission of water and introduce a high level of uncertainty in the accuracy of a model which, as stated in the Groundwater Model report (DEIR Appendix K.3), assumes the geology is homogeneous. Common assumptions such as the correct anisotropic ratio for the groundwater transmission calculations may not be accurate.(Model Review, 3.g.)

Taken together, the groundwater model is seriously deficient with respect to data reliability, initial conditions, and modeling assumptions, calling into question its ability to accurately depict the Project's impacts.

**Grp 7-27** Finally, use of modeling in a fractured rock system has limited value. Modeling that relies upon uniform rock, which is consistent from place to place, behaves in a more predictable fashion than rock that is in bedrock systems having multiple faults and irregularities. It is critical to provide for long term monitoring and extended protections due to the challenges inherent in modeling groundwater in this complex hydrogeologic setting.

The revised DEIR must provide accurate and adequate information and comprehensive analysis to determine the extent and the severity of the impacts upon groundwater resources and wells. Without this analysis, the revised DEIR must identify such impacts as significant and unavoidable.

WELLS AND WATER MONITORING

**Grp 7-28** 16 The DEIR inappropriately defers the collection of additional water monitoring data to the future.

The DEIR acknowledges that more groundwater level data is needed to assess the potential impacts of the proposed Project on groundwater levels. Mitigation Measure 4.8-2(a)(4) (DEIR section 4.8 pg 67) states that this needed water assessment be conducted "once dewatering of

the underground mine workings commences." This is internally inconsistent and would not be achievable. Once dewatering begins, it will be impossible to measure baseline levels. Consequently, this mitigation measure is impossible to implement. Mitigation measures under CEQA must be achievable, enforceable, and must be capable of actually reducing the Project's impacts.

The DEIR inappropriately defers the collection of additional data (via a Groundwater Monitoring Plan) to the future. CEQA does not allow the deferral of important studies necessary to characterize impacts because it denies decision-makers the information they need to make well-reasoned decisions regarding the viability and impacts of a Project.

Groundwater monitoring networks will need to be established in advance of the Project, and the resulting data will need to be included in the revised DEIR. The consequences of not committing to full compliance with General Plan Policy 2.17 are dire for local property owners who rely on groundwater. (Baseline)

17 Relying on fifteen monitoring wells to estimate the impacts on all water supply wells around the mine area is inadequate.

**Grp 7-29**

The DEIR relies on fifteen monitoring wells to estimate impacts on water supply wells but it does not explain how it arrived at this number of wells or their location. In complex fractured bedrock spread out over thousands of acres, monitoring water levels at fifteen locations could not possibly provide the needed data to ensure that groundwater impacts to hundreds of existing water supply wells in the Project vicinity are immediately identified and mitigated (Baseline,p12).

The revised DEIR must provide reliable data regarding the Project's monitoring regime in order to provide an accurate accounting of groundwater impacts.

18 Potential impacts to wells are underestimated and the proposed mitigations are inadequate.

**Grp 7-30**

The DEIR relies on a Well Mitigation Plan to allegedly protect wells from mining impacts. The Nevada County General Plan (Policy 17.12, item 1) states that:

*"In approving mining projects which **according to expert opinion** may threaten the existing quality or quantity of surface or subsurface water which supply adjacent homes and businesses:*

*1) The County shall require the operator to guarantee a comparable supply of water to such homes or businesses through accessible forms of security or alternate sources of water."*

In contrast to the opinion of the DEIR consultant EMKO (DEIR Appendix K.9, p1), numerous experts have stated that there is the potential for a significant threat to water supply for wells in the area beyond those identified in the DEIR. Notably, Baseline Engineering unambiguously states that, *"...it is Baseline's expert opinion that the project may threaten the existing quality or quantity of surface or subsurface water which supply adjacent homes and businesses in a much wider area than is indicated in the DEIR."* (Baseline)

The DEIR relies on a Well Mitigation Plan to purportedly protect wells from potential mining impacts. Yet, the Well Monitoring Plan does not demonstrate that impacts would be mitigated.

BIOLOGICAL RESOURCES

19 Proposed mine dewatering activities have the potential to have a significant impact on dependent biological resources.

**Grp 7-31** The DEIR fails to adequately address biological and aquatic resources, and hydrological impacts to those resources.

The DEIR's biological surveys exclude an entire reach of South Fork Wolf Creek (SFWC). Species of special concern are inadequately considered and qualitative data for benthic macro-invertebrates (BMI) is missing. (Wolf Creek Community Alliance (WCCA), Benthic Macroinvertebrate Analysis, 2007)

Aquatic resources are excluded through an inaccurate hydrological assessment of the full length of SFWC, ignoring the connectivity of the creek upstream and downstream of the culvert on the Mine property, thus failing to consider the movement of trout and other aquatic species.

**Grp 7-32** Hydrological impacts due to mine dewatering into SFWC are inadequately studied, mischaracterized, or not considered. The initial dewatering rate of 2500 gallons per minute (gpm) would be followed by 80 years of subsequent operational dewatering at 850 gpm and as much as 2500 gpm. The DEIR fails to adequately consider this long-term higher rate of

**Grp 7-33** discharge. Nor does the DEIR consider the seasonality of stream flow, loss of streambed or streambank habitat, changes in temperature, differences in Specific Conductance (EC), and

**Grp 7-34** habitat for BMI. Drawdown of the water table due to dewatering is also underestimated and its impacts to meadow, wetland, and forest habitats are not considered. Further, the DEIR fails to consider chronic and cumulative impacts to BMI, trout, and other aquatic species, including

**Grp 7-35** special concern amphibians. (WCCA)

Overall, because the DEIR does not adequately address biological and aquatic resources or sufficiently analyze hydrological impacts, this document must be revised.

20 Mine water discharges would overheat South Fork Wolf Creek.

**Grp 7-36** Mine water temperature ranges between 14 and 15 degrees Celsius. The Project must not change the temperature of water discharged into the South Fork of Wolf Creek by more than 5 degrees Fahrenheit (2.8C) per NPDES requirements.( DEIR Appendix K.2, p108) Water from the mine will be pumped into the seven acre treatment pond. From there it will be run through the treatment facility and discharged into the creek. The DEIR's Hydrology study provides only a few data points (April and August of 2019 and Jan 2020) to determine the range of values for the creek flow and temp. However, over 15 years of monitoring by WCCA provides data

indicating that the temperature of the creek often falls substantially below 10C, and that these temperatures commonly occur during low flow times.

The revised DEIR must include studies that reliably predict the mine water's outflow temperatures from the treatment pond into SFWC. To do this, the EIR must include thermal modeling of the treatment pond, including the temperature impacts due to the treatment processing plant, flow through rates, cooling under different weather conditions, solar gain, evaporation, precipitation, etc. In order to avoid impacts to the SFWC and the species that inhabit the Creek, the revised DEIR must demonstrate that the discharge temperature and flow rates, combined with the temperature and flow rates of the stream over a range of conditions would not result in temperature changes in the stream in excess of 2.8C (5F) degrees.

GREENHOUSE GAS EMISSIONS AND ENERGY

21 The DEIR relies on an arbitrary threshold for greenhouse gas emissions.

**Grp 7-37**

The DEIR states greenhouse gas (GHG) emissions from mine operations would be just under 10,000 metric tons (MT) of GHG carbon dioxide equivalent ( CO2e) per year. This number was chosen as a bright□line threshold based on other air districts in California that included Placer County, Sacramento Metropolitan Area, the Bay Area and Southern California. Neither the Northern Sierra Air Quality Management District (NSAQMD) nor the County have adopted numerical thresholds of significance for GHG emissions that would apply to the Project. The DEIR does not discuss the justification provided by each air district for adopting the 10,000 MT CO2e per year threshold, nor does it provide substantial evidence for applying this threshold to the project to demonstrate how it will achieve a fair share of the statewide GHG reductions goals for 2030 and beyond.

The DEIR must be revised to identify and provide justification for a GHG threshold of significance that will achieve the statewide GHG reductions goals for 2030 and beyond over the proposed 80 year lifetime of the mining permit. (Baseline)

22 The DEIR underestimates GHG emissions from haul trucks.

**Grp 7-38**

The DEIR states that the Centennial Industrial Site will be used for mine waste dumping to form "engineered fill" during the first 5 years of mine operations. The DEIR's analysis assumes that the Centennial Site remediation to remove toxic mine waste would be completed before the mine opens. However, since the remediation of the Centennial Site is not included in the DEIR analysis and, as indicated in the Project Description, may not be completed in any specified timeframe, "...it is speculative at best to assume that the Centennial Industrial Site will be available for fill placement." (Baseline)

To accurately account for the Project's GHG emissions, the DEIR should have assumed an additional five years of offsite hauling at the beginning of operations. This additional hauling would generate significantly more emissions than disclosed in the DEIR. This also holds true for criteria air pollutants as well.

The GHG emission should be updated in the revised DEIR to include the prospect of the Centennial Site being unavailable for mine waste dumping.

---

23 Mining energy requirements would eliminate gains attained through the Nevada County Energy Action Plan.

The Nevada County Energy Action Plan calls for a 51% reduction in GHG emissions for electricity use by 2035, which is in close alignment with state goals. The Plan calls for residential energy reduction savings from building efficiency of 42 million kilowatt hours per year ( kWh/Yr).

The DEIR states the amount of electricity required to operate the mine would be approximately 49 million kWh/Yr (DEIR p. 4.3-59), which would erase any residential electricity savings attained by the Plan.

**Grp 7-39**

The total non-residential electricity use of the county in 2017 was 53 million kWh/Yr. So, GHG emissions from this this one mining project alone would almost equal all other non-residential electricity use in the County and wipe out the projected 9 million kWhYr non-residential building efficiency savings.

Asking residents and business owners to cut down on their use of electricity while allowing the GHG emissions from the mine would be highly counter-productive and unfair. The DEIR must explain how the project intends to comply with the emission goals of the Nevada County Climate Action Plan.

The California Air Resources Board 2017 Climate Change Scoping Plan stated: "Achieving no net additional increase in GHG emissions, resulting in no contribution to GHG impacts, is an appropriate overall objective for new development." Given these facts, the DEIR must establish a net zero threshold for new GHG emissions from the Project and declare the project has significant and unavoidable impacts.

---

NOISE AND VIBRATION

**Grp 7-40**

24 Nighttime Noise Impact is Not Adequately Addressed.

The analysis "Acoustical Comments on Draft Environmental Impact Report, Salter Project 22-0039" (Salter) provides comments on the DEIR's analysis of the noise and vibrations for the Project.

Salter determined that nighttime noise is not adequately addressed in the DEIR. The DEIR outright dismisses the potential for noise impacts due to sleep disturbance and inappropriately excludes this consideration from the DEIR analysis. The combination of nighttime industrial activities amongst a community that currently enjoys low ambient noise levels represents a significant risk for Project noise to impact the community, annoy residents, and cause sleep disturbance.

A revised DEIR should provide a comprehensive analysis of nighttime noise impacts, identify these as potentially significant impacts, and identify appropriate mitigation, including limitations on nighttime noise, to protect nearby residents. (Salter)

25 Engineered Fill Operation Noise is Underestimated.

**Grp 7-41**

The DEIR underestimates operational noise from the Project's engineered fill operations (Impact 4.10-2). This 5 to 6-year long activity could generate noise levels at least 10 to 18 dB higher than predicted in the DEIR. This is a significant deficiency in the impact analysis. As such, the project's noise levels could be 20 to 35 dB louder than current median/background ambient noise levels, causing a severe impact. In addition, in several instances, the DEIR fails to adequately address impacts to sensitive receptors located farther away from existing roadways that currently have a lower background noise (Salter). The DEIR must be revised to correct these deficiencies and omissions.

26 Blasting Vibration Impact is Not Adequately Addressed.

**Grp 7-42**

The DEIR fails to adequately evaluate blasting vibration impacts (see Impact 4.10-4). Blasting operations have the potential to subject nearby residents to "strongly perceptible" and borderline "unpleasant" vibration on a regular basis for the rest of their lives. These perceptible and unpleasant vibrations must be considered a significant impact in the DEIR.

In particular, the DEIR fails to include crucial guidance from the U.S. Office of Surface Mining Reclamation and Enforcement Blasting Guidance Manual restricting blasting vibration during evening and nighttime hours. If blasting must be allowed at these sensitive times, the DEIR must incorporate adequate mitigation with a notably stricter limit at all sensitive receptors (Salter).

HAZARDS

27 Potential mine flooding and worker safety from groundwater occurrence in mine workings.

**Grp 7-43**

In the DEIR's discussion of the Union Hill Mine, it is noted, "The Union Hill Mine workings are within 95 feet to 180 feet of workings of the Brunswick Mine at three to four different levels. During the post WWI period, the combined Idaho-Maryland Mine workings were completely dewatered. In 1956, the water level at the Union Hill Mine was reported to be within 20 feet of

the top of the shaft, suggesting that the complete dewatering of the adjacent mine workings resulted in no more than 10 to 20 feet of water level decline in the Union Hill Mine."

There are two important points to note in this discussion, (1) the Union Hill Mine is very close to the Idaho-Maryland at several levels; and, (2) there has been a possible weak hydraulic connection between the two mines, which is only logical.

There is no discussion in the DEIR of the potential impacts for the Idaho-Maryland Mine if flooding were to occur during mining. According to ITASCA's report (DEIR Appendix K.3, Figure 2-3), there are extensive abandoned mine workings above and adjacent to the Idaho-Maryland Mine that would remain flooded after the Idaho-Maryland is dewatered. If a conduit between these two mines were to open, for instance due to the widening of a fracture related to blasting vibrations or a seismic event, the flood of water into the Idaho-Maryland could be rapid and catastrophic for anyone working in the mine.

The DEIR must be revised to evaluate the potential risks of flooding during mining operations, including potential risks to mine workers. (CSP2)

28 Voluminous updraft from Mine ventilation air discharge may condense to form a water vapor cloud or fog resulting in a potential air traffic hazard.

**Grp 7-44**

The mine ventilation system would discharge 200,000 cfm of saturated air at 68F degrees from the top of the headframe with an upward velocity of 7.7 ft/sec. The headframe is located within the airport safety zone. Under some weather conditions, this large volume of air exhaust may form a persistent cloud plume, or fog, which could be a potential visibility hazard for aircraft. Also, the large mass of air moving upwards may create turbulence. In addition to aesthetic impacts, the DEIR should assess the potential hazards to aircraft of this large volume of saturated air (see MineExhaustMoisture report, attached as a reference to this letter).

29 The DEIR's evaluation of seismic hazards due to faults and mining is inadequate.

**Grp 7-45**

The mine project would target potential ore bodies that are more or less bounded by the Morehouse fault, the 6-3 fault (Weimar), and the Idaho fault, as well as numerous lesser faults. While the faults in this area are designated as being in a type C fault zone, with low seismicity and a low rate of recurrence, the DEIR does not analyze the effect that a seismic event would have on the mine or workers in the mine. (For further details, see FaultingHazards, attached as a reference to this letter) .

Throughout the 80 year life of the proposed project, expansion of mine works will remove 30 million tons of rock mass, and change the overall competency of the surrounding bedrock. In addition, several million tons of mine waste will be positioned over or near the faults. Finally, at the end of mine operations, the mine will re-flood, leading to an additional potential increase in seismic activity due to the re-introduction of hydrostatic pressures. (FaultingHazards)

The seismic reports discussed in the Geology section of the DEIR are not up to date and, even if updated, would not meet the requirements for a probabilistic seismic site analysis. (CSP2, p7)

**Grp 7-46** The revised DEIR must include a complete and comprehensive analysis of the potential hazards due to seismic activity as a result of the Mine Project.

## Conclusion

**Grp 7-47** The DEIR lacks critical information necessary to identify all potentially significant impacts associated with a large underground mining project close to a populated area with complex groundwater and geologic conditions, and accordingly, fails to comply with CEQA requirements. As detailed above:

- The toxic legacy of the Idaho Maryland Mine at the Centennial site is incorrectly assumed to be already remediated in the DEIR for five resource areas, which leads to an underestimation of impacts, particularly in biology and hazards impacts;

**Grp 7-48**
- Health issues due to air quality and noise impacts are vastly underestimated;

**Grp 7-49**
- There is no proposal for managing the stockpiling and containment of waste and related runoff on site;

**Grp 7-50**
- The DEIR defers analysis of mine waste analysis;

**Grp 7-51**
- Asbestos and silica release are not evaluated;

**Grp 7-52**
- The groundwater model has significant errors, omissions, and is unreliable leading to a gross underestimation of groundwater and well impacts to nearby residents;

**Grp 7-53**
- Well monitoring is inadequate to evaluate impacts to the hundreds of existing wells in the project vicinity.

**Grp 7-54** The DEIR lacks an accurate project description, lacks data and analyses needed to make informed determinations, and fails to provide effective and feasible mitigation measures. For these reasons, the document is inadequate under CEQA. The DEIR should be revised and recirculated to comply with CEQA.

Dear Matt Kelley,

Please include these comments to the Idaho-Maryland Mine DEIR.

## Review of the Idaho-Maryland Mine DEIR Groundwater Model

This review of the predictions on the impacts to groundwater and wells for the Idaho-Maryland Mine is based primarily upon two DEIR documents: "Appendix K.2_Groundwater Hydrology and Water Quality Analysis.pdf" by Emko (EMKO) and "Appendix K.3_Groundwater Model Report.pdf" by Itasca (ITASCA).

### 1. Mine water Outflow Issues

The Hydrology Study uses data on mine water outflow rates that are based on approximations and estimates taken on only a few widely separated instances. These data are contradicted by more reliable historical data.

**a) Estimated Mine Drain Flow Rates per DEIR**
There are 3 identified discharge points for the mine at Wolf Creek: The Eureka Drain (ED-1), the 24" East Eureka Shaft Drain from the Navo building (IMD-1), and the East Eureka Shaft steel pipe from the Navo building (IMD-2). All drains are at or below 2502 feet elevation. A fourth potential drain is questioned as to source.

**Grp 7-64**

The ITASCA groundwater model used the following outflow data that was provided in EMKO Section 3.3.4, summarized here:

Flow data, ED-1:
"...in the range of 100 gpm (Condor, 1994)
"...only a few gpm" (EMKO Feb 2018, Dec 2018)
"...in the range of 20 to 25 gpm" (EMKO, April 17, 2019)
Flow data, IMD-1:
"...to be about 60 gpm." (Todd Engineers, 2007)
"...consistent with Todd..." (EMKO Feb 2018, Dec 2018)
"...approximately 100 gpm." (EMKO April 17, 2019)
Flow data, IMD-2:
"...in the range of 1-2 gpm." (EMKO Feb, 2018)
Flow data, D-1:
"...only a few gallons per minute" (EMKO? Feb, Dec 2018, April 2019)

This scant data is the basis of the outflow values of 60-125 gpm reported in the DEIR. [DEIR 4.8-19]

In order to establish a viable model of the hydrology for the mine, these critical questions should be unanswered:

- What is the actual measured outflow?

**Grp 7-65**
- How does it vary seasonally?

**Grp 7-66**
- What are the current outflows at the Wolf Creek drains under the current model?

**Grp 7-67**
- How do the model flows compare with the measured outflows?

**b) Measured Mine Drain Flow Rates per Historical Records**

More thorough and inherently precise measurements were provided by an earlier study. According to the Technical Assessment by James Askew Associates Inc, which was prepared in 1991 for the 1995 Empire Gold permit application to dewater the mine:

**Grp 7-68**

*"ED-1 is estimated to be discharging 100 gallons per minute [gpm] of water. IMD-1 and IMD-2, which are located about 25 ft upstream of ED-1* **discharge in the range of 500 gpm to 1,200 gpm depending upon the season. Weir measurements are made by NID at IMD-1.** " [Askew, Section 5.3.2 Hydrology - Surface Water, pg 5.3. ]

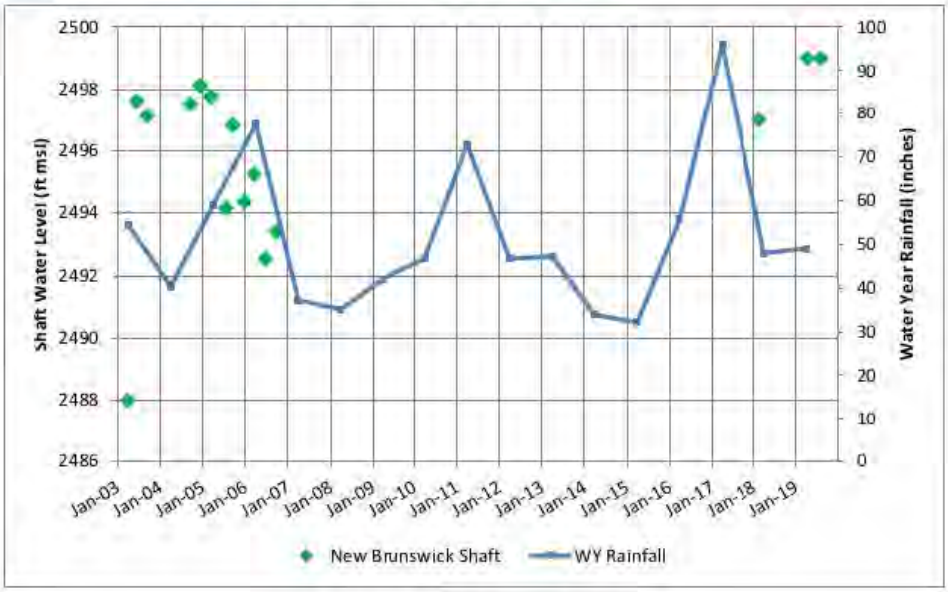
This implies that the total current discharge from the mine into Wolf Creek is likely in the range of 600 to 1300 gpm, depending upon the season, or almost ten times the amount reported in the DEIR.

The reported outflow in the EMKO report appears to be grossly understating the actual outflow. ITASCA did not report any water/mass balance for any of their simulations. Inherent in any numerical simulation, like ITASCA's, is a water balance (so that balance errors can be evaluated):

**Grp 7-69**
- Year-round accurate outflow measurements taken daily should be collected.
- Data should be collected for several years, including at least a year with normal rainfall and a year with low rainfall, in order to establish a baseline for groundwater modeling and impact assessment.
- Assessment of the fractional contributions of surface runoff and percolation can be better achieved by outflow volume logging.
- Water balances for the mine area should be provided and verified with the model.

## 2. Mine Water Inflow and Transmissivity Estimation Issues

**a) The analysis of seasonal measurements of the level of water in the mine is flawed and does not support the transmissivity assumptions used in the model.**



The Hydrologic study concludes that there are no correlations between the elevation of the water surface in the mine and the seasonal precipitation. It uses this point to support the position that there is little volumetric transmission of the water from the upper five hundred feet of fractured rock down into the mine. There are a number of reasons why the mine water level data is not useful as a basis for determining transmissivity.

**Grp 7-70**

First, note that the mine is flooded, and Measurements were taken in 2003-2007 and 2018-2019 at the New Brunswick (NB) Shaft (EMKO Fig 3-7). The water level in the mine, averages 2497 ft elevation. A few measurements have been lower, with one at 2488, and they have a maximum of around 2499 feet.
Second, note that minewater drains out of the mine at the drains located along the main branch of Wolf Creek, which is over 1.5 miles away from the NB Shaft: the East Eureka drain (IMD-1 ) is at 2497 ft elevation. A diagram of waterflow through the mine is in Figure 3-20 (EMKO).
**Mine water level data** - EMKO argues that the levels of water in the NB Shaft are independent of the seasonal rainfall and provides a graph showing both rainfall and NB Shaft water levels. (see Figure 3-7 below) Unfortunately, the NB Shaft data are very limited. Only about 15 measurements are provided. (Additional issues with the interpretation of the data are discussed in 4, below. ) Note that of these, nine are at or above 2497', which is the drain level.
**Obviously, if the water level exceeds the drain level, the water will flow out.** The higher the NB Shaft level, the higher the rate of drain outflow. Thus, water levels in the NB Shaft would not provide a valid assessment of the amount of water flowing into the mine unless the outflow is measured.

Additionally, inflow and outflow is complicated by the fact that the near-surface region around the shafts in the area may be quite fractured and/or weathered and so seepage could occur through those more permeable zones.

***Figure 3-7 Comparison of Shaft Water Levels with Rainfall***

[3] IMMC used an estimated collar elevation of 2,750 ft msl. Since the collar elevation has been confirmed at 2,756 ft msl, the water elevations reported by IMMC (2007) have been increased by six feet in this report.

[4] One measurement, from June 2004, had a reported elevation of 2,581 ft msl, or about 100 feet higher than the other 12 measurements made by IMMC (2007). Review of the data presented by IMMC (2007) suggests that the anomalous June 2004 elevation may be due to a data recording or reporting error. Thus, it is not considered further in this report.

Grp 7-71

Grp 7-70

**b) Invalid interpretations of seasonal precipitations vs mine water levels.**

The seasonal interpretation of the New Brunswick Shaft water levels data is flawed. Even without considering the fact that the mine drain outflow rates will create an upper limit to the change in water levels in the NB Shaft, the data does not support the claims made in the EMKO report. EMKO claims that the data "*...demonstrate that the variations in the water level in the shaft do not occur on a seasonal basis, and that there is not a consistent correlation between water levels in the shaft and rainfall.*" [p30, and Figure 3-7]

There are several errors to this reasoning. First, note that data is sparse, with only 12 samples over a four year period in 2003-2006, plus a single sample in 2018, and two samples in 2019. Also note that the data is taken at

various times of the year, making direct year to year correlations limited. Also note that the annual rainfall year is based upon precipitation from October thru September, and a single data point for each year's rainfall is apparently placed on April 1, in the middle of that year's rain season. (Figure 3-7).

The chart lacks sufficient granularity to be useful. For example, a year's rainfall may be above average, but an NB Shaft measurement taken in December of that year may reflect that the first few months of the rainy season and the preceding last 6-9 months of the prior year's seasonal rainfall, which could be below average even though the rainfall year was recorded as above normal due to rains after December for that year.

In order to detect variation seasonally, it is more useful to look at the total rainfall in the months preceding any particular NB Shaft measurement. Thus, for the NB Shaft value at ~2497' elevation on around Feb 2018, the total rainfall from June 2017 through Feb 2018 was only 25.98". This is below normal. This correlates with a lowered level in NB Shaft. But the higher value of the 2017 total rainfall year reflects higher precipitation from more than 9 months earlier, giving the false impression of non-correlation.

**Grp 7-73**

Note also that the 2019 precipitation data is invalid according to precipitation records. The 2019 precipitation should be graphed at 68.15 inches, the correct precipitation for that period. But it is graphed at an incorrect value of 48 inches. Correcting the graph would show a direct correlation between higher precipitation and NB Shaft levels.

**Grp 7-74**

In addition, in close examination of the data for 2005, there is a clear drop in levels between the late Winter sample and the mid Summer sample followed by a Fall rebound. Also, again in 2006, there is a clear drop from late Winter to mid Summer followed by a rebound. Thus, data from both of those years **seems to imply that there actually is a seasonal correlation.**

Complicating this, an unknown amount of surface water or near surface percolation from seasonal precipitation may impact mine water inflows. However, the model report assumes that the entire seasonal pumping variations as reported in historical records are from surface leakage and not due to transmission through the bedrock: "*...during the rainy season, total pumping would probably be in excess of 900 gpm, perhaps in the range of 1,400 to 1,600 gpm. This estimate is based on the observation that the rainy season flows would increase by approximately 500 gpm for the historical Idaho-Brunswick Mine. [Itasca, pg 23 (35/93)]* ITASCA goes on to assume that this is not an indication of any bedrock transmissivity: "*...the excess inflows are due to surface-water runoff and percolation.*"

**Grp 7-75**

It seems surprising that an argument would be made that there is no seasonal correlation between mine water levels as a basis for determining low transmissivity while failing to consider that there are maximum water levels in the mine due to the drain elevation, and then acknowledge that there is a seasonal variation in pumping rates. Why wouldn't seasonal variations in pumping rates show up as seasonal variations in the mine water levels?

However, all of this may be a moot point because water migration downwards to depths may be delayed. Latency in water conductance time from surface percolation through the bedrock to depths may take a year or two and produce a smoothing effect on variations in mine water levels. This should be taken into consideration. Data for the years prior to 2003 would be needed to make that assessment.

Looking at the graph based upon annual precipitation over multiple years, there does appear to be a downward trend in shaft levels from 2004 to mid 2006. And the annual precipitations were notably below normal from 2003 to December of 2005. So the graph seems to show a multiyear downward trend in the NB Shaft levels with a clear seasonal variations signal also showing in the measurements.

**Grp 7-76**

In conclusion, the given EMKO conclusions from the comparison between NB Shaft water levels and seasonal precipitation using figure 3-7 do not hold water. The following are needed:

- Year-round logging of mine water level and outflow should be collected.

- Data should be collected for several years, including at least a year with normal rainfall and a year each with low and high rainfall, in order to establish a baseline for groundwater modeling and impact assessment.
- The data from the outflow and the data showing changes in mine water level can then be compared with granular rainfall data to legitimately make an assessment of the amount of seasonal variation in mine water inflows.
- The data could then be used to provide an estimate of transmissivity from the surface.

**c) Data from monitoring of wells is old, limited to a few years, and with no well owner's usage data.**

**Grp 7-77**

Monitoring of wells was conducted in 1995-2001, 2003-07 ((DEIR Appendix pg 4.8-11))
Well log records show seasonal variability but there is no data provided on how much of the well water level changes are due to dry season water usage and how much is a reflection of the actual lowering of the ground water level overall.

No recent well monitoring was conducted during drought years, and no assessment was made on the long term predicted impacts of climate change. These impacts include: warmer weather, changing rainfall amounts, shifting of rainfall periods, as well as consideration of water usage changes by property owners due to drought.

**d) Surface Infiltration - Groundwater Recharge**
**The study fails to account for a substantial decrease in groundwater recharge from precipitation as a result of planned project development.**

The EMKO hydrology report (Appendix K.2) claims that groundwater recharge due to surface infiltration would be essentially unchanged: "Thus, the project would not result in any appreciable new areas of compacted soils or impermeable surfaces that could substantially restrict or otherwise interfere with groundwater recharge." (p 121-122)

The analysis of changes in surface infiltration needs to include changes due to the engineered fill which covers 31 acres on the Brunswick site. In addition, infiltration would be reduced on the Centennial site, where the engineered fill will reduce permeability over 44 acres, bringing the total of near-impermeable engineered fill to 75 acres.

**Grp 7-78**

Even if Rise Gold abandons the use of the Centennial site for mine waste dumping, as in DEIR Alternative 2, there is a cumulative impact from the planned DTSC cleanup of reduced groundwater recharge in the areas of remediation tailings placement, based upon the draft RAP. (Note, the Final RAP has not been prepared.)
From DTSC Remedial Action Plan draft, p27 (52 of 623):

*"The evaluation considers the on-site placement of tailings with elevated metals concentrations at a location that is not subject to surface water erosion or leaching (e.g., engineered fill with appropriate surface and subsurface drainage controls), and assumes that the engineered fill will have a simplified environmental attenuation factor of 100 for protection of surface water and groundwater quality, pursuant to the Designated Level Methodology (DLM; RWQCB, 1989 Jun)."* and
*"Consolidation and capping of the tailings as engineered fill with appropriate surface and subsurface drainage controls at a location away from Wolf Creek* **will significantly reduce the potential for storm water erosion and infiltration.**"

In addition, the impervious surfaces of the Brunswick site will increase by 6 acres. (DEIR Project Description p14):
*"The site currently has approximately 9 acres of impervious asphalt paving from previous land uses. Some of the existing asphalt areas will be removed and some will be reused. After completion of construction, the impervious surfaces and buildings will cover a total of approximately 15 acres of the Brunswick Industrial Site"*

In total, 81 acres will have a reduced infiltration which should be included in the ground water calculations.

**e) Estimated surface areas in the mine works have limited reliability**

Estimates of groundwater transmissivity rely in part upon estimates about the subterranean surface area of the mine works as compared to the amount of mine water outflow. In the hydrology report the typical drift dimensions are assumed to be 7.5ft x 8.5ft (WxH) [pg 12]. However, in prior studies (DEIR Appendix F.2, Hydrogeological Overview, Geosolutions, 2008, p 9) 6ft x 6ft is used as the average cross section for stopes, raises, winzes, shafts, and drifts. Further details followed:

"*Because of the type of equipment utilized in mining during early to mid 1900s beneath Grass Valley it is reasonable to assume that drifts now located throughout the Idaho-Maryland mine have a cross sectional dimension of about six feet wide and six feet high.*" (p17)

**Grp 7-79**

The following must be explored:

- Given this contradiction, what is the justification for using the larger size for the surface area estimates?
- What is the source of the 7.5ft x 8.5ft measurement?
- How would the reduction of surface area per running foot from 24.5 ft (2H +W) to 18ft, or about 25%, affect the assumptions of transmissivity and the overall hydrological model?
- For the same amount of measured water outflow, a decrease in the transmitting surface area indicate a corresponding increase in transmissivity of bedrock.
- The model should use those higher values as a starting point.

**3. Groundwater Model Elements**

**a.) Additional drawdown from the proposed new access shaft**

A new access shaft is proposed close to the creek, but a cone of depression of groundwater levels like the one indicated at the New Brunswick Shaft is not shown. This new shaft is particularly worrisome because of its proximity to South Fork Wolf Creek.

The following questions must be answered:

**Grp 7-80**

- Was the new access shaft included in the Itasca ground water model?
- What is it's precise location? The shaft should be located on all maps.
- How far is it from South Fork Wolf Creek, a perennial stream?
- Is it within 100 ft?
- Was there analysis of the impact of the groundwater caused by the significant 60 ft deep excavation needed to build a permanent access shaft?
- Will this lead to more draw down of near surface groundwater?
- How will the creation of a large excavation and a new access shaft impact the near surface ground waters that feed SFWC?

**b.) Does the model include numerous existing near surface features from the historical mining?**

There is no indication that the many other near surface features of the Idaho-Maryland Mine were included in the analysis as additional areas of groundwater drawdown and/or conduits for water movement. In addition to the existing NB Shaft, the technical study "near surf.." identifies 14 other shafts, drifts, and drain features which pass through the more transmissive top few hundred feet of fractured bedrock. Each of these features will potentially impact the model by increasing transmission out of the top fractured rock zone. And most of them currently have water levels that are close to the surface. Hence the impacts would be noteworthy.

**Grp 7-81**

In addition, there are likely additional unidentified legacy mine near surface features which may affect the model. For example, note the unexplained sinkhole area noted in "Geotechnical Assessment of Near Surface Mine Features":

*"The property owner indicated that approximately two years ago settlement of the ground surface was observed near the shaft location and was backfilled with boulders and soil. No documentation available. Additional settlement at the shaft location, measuring approximately four feet by five feet wide and 18 inches deep, was observed in February 2020." (DEIR Appendix H.6, p5)*

There are numerous other nearby mines, both documented and undocumented. A survey of mines adjacent to and nearby, and a survey of reported sinkholes or other features identifying mining activity should be conducted to determine whether other near surface mine features may impact the groundwater model.

**c) Did the mining model include all potential mining areas?**

**Grp 7-82**

The model assumes the areas to be mined will be confined to very limited areas at depths greater than 1000' (DEIR Appendix K.3, pgs 11, 30). However, the mineral rights provide no restriction to mining anywhere within the 2585 acres and to within 200' of the surface. Furthermore, mining activity is indicated for within 500 feet of the surface:

*"New underground workings, except for the service shaft and new ventilation raise, would be below 500 feet of the ground surface."* (DEIR 3.19)

The groundwater model needs to assume that all areas within the mineral rights zone could be mined.

**d) The model simulations were conducted with the assumption that mining would be only for 25 years.**

All computer models that attempt to simulate real world conditions are based upon assumptions. Even minor differences between input data and actual real world conditions can result in errors that increase exponentially over time. The longer that the computer model is run, the greater the potential for deviation from actual outcomes.

**Grp 7-83**

From page 23 of "Appendix K.3_Groundwater Model Report" by Itasca: *"The predictive numerical simulations were conducted to assess the potential inflows to the mine workings, the effect on nearby domestic wells, and the potential effects on the creeks in the Mine area during mine development and production* ***between the assumed years of 2020 and 2045 (Year 1 to Year 25), which is the current mine plan."***

The permit request is for 80 years. Simulations in the model extended the calculations for 40 years to a total of 65 years. This is still short of almost 80 years of mining expansion.

The following must be considered:

- The model should be run for 80 years if possible.
- The model authors should justify the simple extension of the run times, along with an analysis of the reliability of a model over such an extended period of time.
- Examples of actual real life validation of similar numerical simulations over this extraordinary length of time and similar complex geological conditions must be provided.

**Grp 7-84**

- What is the model predictive success rate?

**Grp 7-85**

- How does the range of deviation change over longer periods?

**Grp 7-86**

- In order to assess the relevance and accuracy of the model, a listing of the initial conditions and additional data inputs must be provided.

**Grp 7-87**

- The complete model data used in the simulation is a key assessment component and must be included in the documentation.

**Grp 7-88**

**g) Assumptions of transmissivity and anisotropy ratios based upon homogeneity of the rock are questionable. Faulting compounds the issue.**

The model also relies upon assumptions regarding a K value anisotropic ratio of 10:1 horizontal to vertical conductivity. (Ten times more horizontal groundwater transmission than vertical transmission.) This value for anisotropy is very frequently assumed. It holds up particularly well for sediments and sedimentary rocks that haven't been tilted. It wouldn't necessarily hold for bedrock where most of the permeability is related to fractures.

There are numerous faults in the area. The Brunswick block, which is the primary mass of rock in which the proposed mine will operate, is an immense wedge of rock cleaved by 3 major faults, and numerous lessor subfaults.Within this zone are also numerous lessor faults. The mine project is targeting potential ore bodies that are more or less bounded by the Morehouse fault, the 6-3 fault (Weimar), and the Idaho fault.

The transmissivity through the fault planes may be significantly lower than the surrounding rock, and groundwater movement may be routed by these barriers. In the Hydrogeological Technical Memo prepared by GeoSolutions in 2008 for the Emgold project:

**Grp 7-88**

*"Movement along interfacing rock blocks located within stress fields of this type usually produce grinding and crushing of materials within the interface of those structures. Materials produced by this action are commonly called mylonite and are a fine grained laminated material formed by extreme microbrecciation of the rock along the structural surfaces during movement. Because of the pulverization of these rock materials the mylonite generated by thrusting can behave like clay with very low permeability and hydraulic conductivity. Therefore, it is likely the migration of fluids through these structures will be limited or highly routed along lines or planes adjacent to the faults." (Emgold 2008 DEIR Appendix F.2 pgs 12, 14, 16)*

This implies that the 6-3 fault and Morehouse faults, which trend generally in a North-South direction, may form effective walls constraining the horizontal movement of groundwater. The model uses the concept that groundwater movement is predominantly in the East to West direction. *"all of the geologic units were assigned with an anisotropy ratio (i.e., a K x /K z value) of 10."* [note: x is E-W horizontal and z is vertical]

The assumptions that the bedrock can be characterized by assuming homogeneity is a big assumption on its own, but the complexities of numerous faults which may or may not transmit or block groundwater flow raises the uncertainty to new heights. There are likely other faults east of the project which are not mapped. The model sensitivity analysis was run with the consideration that faults may be more transmissive of groundwater. The opposite case should be evaluated.

**Grp 7-89**

- The groundwater model should be run with faults having significantly lower transmissivity or K values.

**Grp 7-90**

- The model should be run with different anisotropic ratios having proportionally lower horizontal transmissivity.

**Grp 7-91**

- There are numerous lessor faults identified within the I-MTech_Report which should be added to the model. (see https://www.risegoldcorp.com/uploads/content/I-M_Tech_Report.pdf)

**Grp 7-92**

The following must be answered:

- What are the potential impacts when mining activities penetrate or remove portions of an impermeable fault wall?

**Grp 7-93**

- Are there measurable drop offs in groundwater surface topography that would indicate an impermeable or lessor permeable barrier?

**3. Conclusion**

**Grp 7-94**

The ITASCA groundwater model has significant issues with data reliability, initial conditions, and modeling assumptions, calling into question its reliability. The questions raised throughout this report must be answered in the DEIR. In particular, additional model runs should be conducted to verify the reasonableness of the

assumptions of the model in terms of mine water discharge, current well logs, and other more adequately measured data as detailed above. Additional sensitivity analyses should be conducted to look at how changing anisotropic values or applying decreased permeability at the faults would affect the predicted drawdowns. This would increase the likelihood that the model approaches reality.

The unreliability of the groundwater model in this situation cannot be used to conclude that groundwater impacts due to the Mine operations will be less than significant.

Thank you,
Ralph Silberstein, President
CEA Foundation

**IM Mine Exhaust Moisture: Potential Hazard, Aesthetics, and Air Quality Impacts Background**
**CEA Foundation**

Key points:

- The headframe is within the airport restricted area.
- The 200,000 cfm volume of air will exit 24/7 at 7.7 ft/sec, possibly causing turbulence for air traffic.
- Under some weather conditions, a persistent cloud plume or fog may form.
- Exit elevation of the headframe is roughly the height of the surrounding residential hills.
- A SW breeze will move this towards the airport, which is less than a mile away.

The Water Supply Assessment states that the Idaho-Maryland Mine will lose about 40,000 gal per day (gpd) of water due to saturated air venting out of the headframe at the Brunswick site.[1] The exhaust fan in the headframe at 165' above ground will emit 200,000 cfm. It will exit from a 23.52 ft diameter stack with a velocity of 7.7ft/sec. The temperature of the exiting air will be 293.15K, or 20C (68 degrees F).[2]

This large volume of saturated 68F degree air exhaust will potentially form a fog or a moisture cloud plume. Depending upon the rate of mixing, this would occur when weather is cool and the relative humidity is high because the temperature of the exiting saturated air will drop and be unable to carry the excess moisture. This will be much worse in cold weather when the humidity is high. For example, when the relative humidity is 80% and the temperature is 41F, the exhaust plume will need to continuously mix with over 12 times its volume to dissipate. If the temperature drops to 35F, the exhaust will need to be continuously mixing with over 40 times its volume.

**Grp 7-95**

A SW breeze will move this towards the airport, which is less than a mile away. Under some conditions, the cloud may persist. In addition, the exiting air column will also have an upward velocity which may impact air traffic due to turbulence.

**IM Mine Potential Seismic Hazard**
**March 20 , 2022**

**Grp 7-96**

The mine project is targeting potential ore bodies that are more or less bounded by the Morehouse fault, the 6-3 fault (Weimar), and the Idaho fault. Within this zone are also numerous lessor faults, which are not shown in this image from pg 7-6, I-M Tech Report. For reference, note that Wolf Creek, South Fork Wolf Creek, and the Brunswick Shaft near the corner of Brunswick Rd. and East Bennett Rd. are shown below.

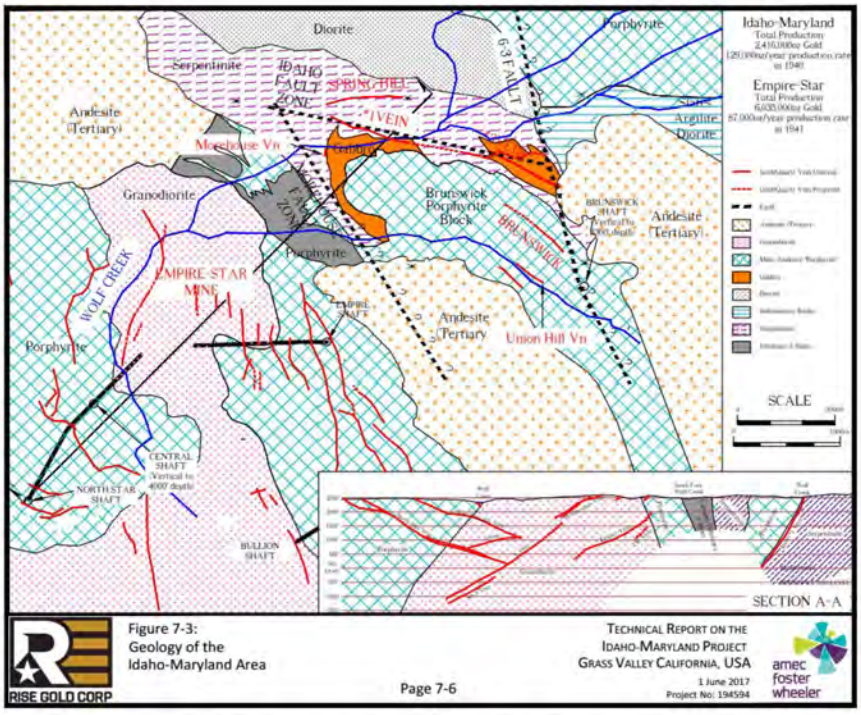

Figure 7-3:
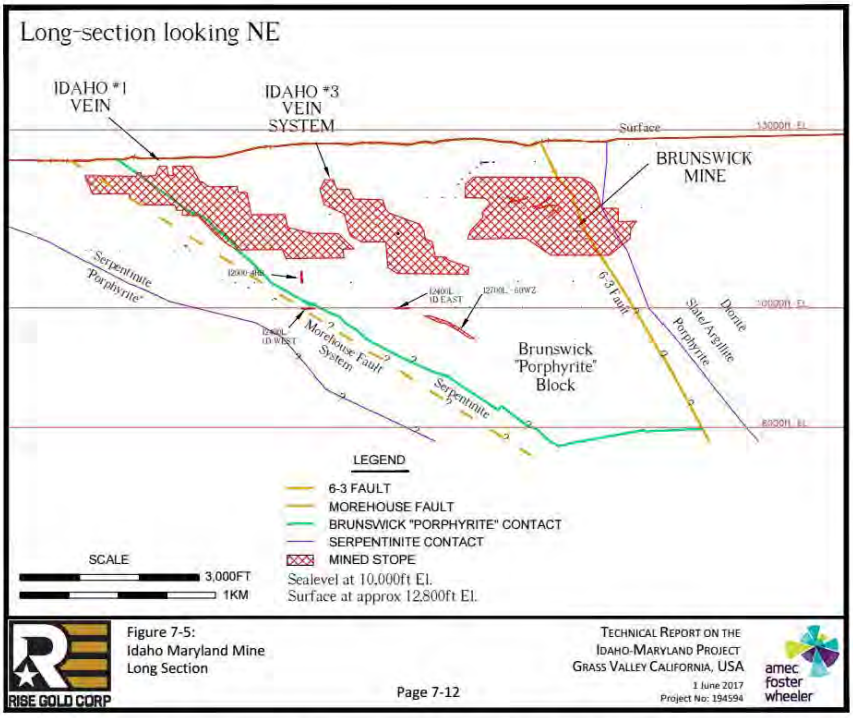
Geology of the
Idaho-Maryland Area

Page 7-6

TECHNICAL REPORT ON THE IDAHO-MARYLAND PROJECT GRASS VALLEY CALIFORNIA, USA
1 June 2017
Project No: 194594

RISE GOLD CORP



amec foster wheeler

As reported in "DEIR appendix H.2_Brunswick Fault Zone MP.pdf" prepared by NV5 dated Jan 16, 2020, the faults in this area are designated as being in a Type C fault zone, with low seismicity and a low rate of recurrence. The report concludes that: *"Fault rupture through the site, therefore, is not considered likely."* (DEIR H.2, p5)

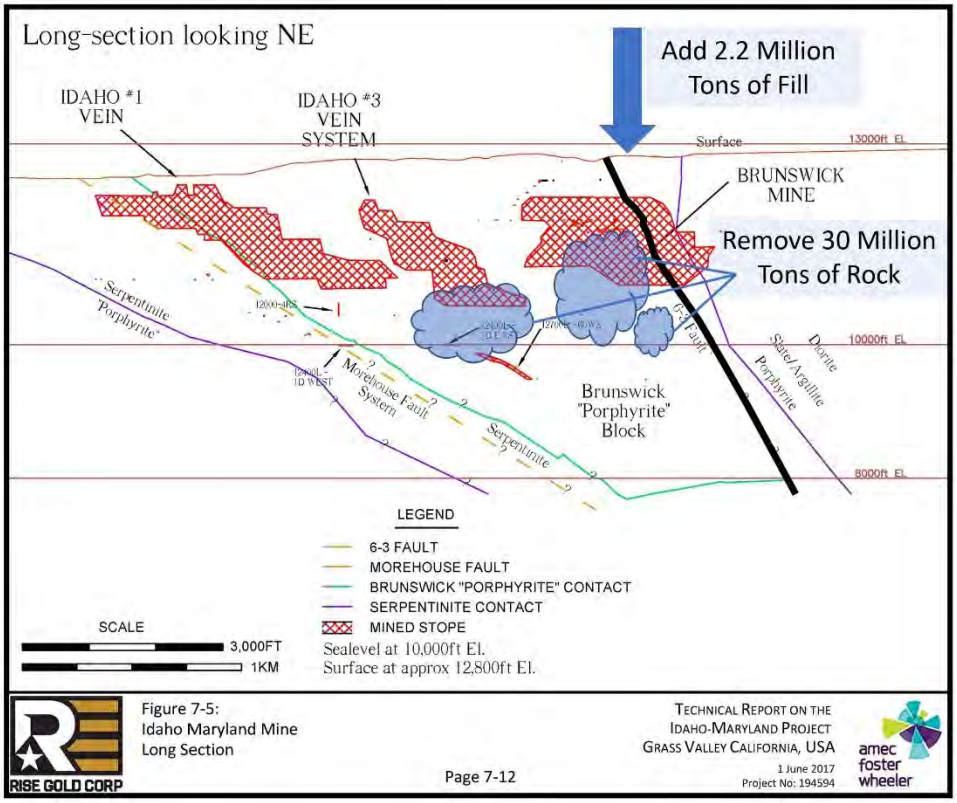
However, no specific seismic study for the mine project was produced, and no further analysis was provided justifying the determination or assessing the potential of impacts from the proposed mining activities on seismicity or hazard risks.

Of note, mining may cause changes to the geologic fault zone stresses in the area. These changes may include localized significant decreases of total stable rock masses, degradation of load bearing capacity, reduced resistance to shear, and in some cases increased mass loading on or near fault lines.

For example, significant increases of localized bedrock loads will result from the disposal of mine waste. According to the plans, dewatering the flooded mine will initially offload about 3.4 million tons of water. Mining for the first 11 years will offload approximately 4 million tons. The surface at the Centennial site will receive about 1.6 million tons from this process, and the southeast portion of the Brunswick site will receive about 2.2 million tons or surface loading. Then, for about 65 years, another 24 million tons will be removed from the mine to be deposited elsewhere. In all, over 30 million tons will be removed from the subterranean mining area.

Particularly noteworthy is the potential for seismic activity on the 6-3 fault in the region of the proposed Brunswick mine waste surface dumping site. The 2.2 million ton mine waste pile loads up the reverse thrust block side of the fault that is over the nearby planned mining operations.

**Grp 7-97**



The above cross section diagram (Page 7-12, I-M Tech Report) shows the 6-3 Fault as a steep yellow line running at a 65 degree slope through the historic Brunswick Mine. Rise Gold has indicated that much of the mining will take place in the "Brunswick Block" located almost entirely to the east (left) of the 6-3 Fault. Using the information provided in the DEIR "Fault Zone MP" (Appendix F.2 p7) the 6-3 Fault is indicated by the red line overlaid on Sheet 1 of the DEIR Project Description, shown here. Notice the location of the mine waste pile, the flat-topped area to the right of the fault line and below (south) of the processing facilities, identified by the circled 8 on Sheet 1.

Throughout the 80 years of mining operations, expansion of mine works by tunneling and stoping will reduce the competency of the surrounding rock structure, vibrations from blasting will take place daily, and finally, at the end of mine operations, the mine will reflood, leading to a potential increase in the seismic activity due to the re-introduction of hydrostatic pressures.

This diagram shows the previous figure 7-5 cross section modified to show the approximate location of the 2.2 million tons of added fill on the right (east) side of the fault. The dewatering and removal of waste rock and ore will be mostly on the left (West) side of the fault.

**Grp 7-98**

**Grp 7-99**

A geological study of the seismic risks, including the risks from the proposed dewatering, mining, and mine waste dumping should be conducted and included in the DEIR addressing the following:

- How will the mining activities impact the seismicity of the area? **Grp 7-100**
- Will the integrity of near surface historical and proposed mine works be impacted by loading? **Grp 7-101**
- All buildings within the fault zones of the faults should be mapped in relation to the faults.
- An evaluation of the lessor faults as identified in the I-M Tech Report should be conducted. **Grp 7-102**

RS 3/20/22

/// calcs ////
[engineered fill: 1000 tons/day 20tons/truck x 50 trucks/day
5 years at centennial = 365,000tons x 5 = 1,825,000 tons or 1.8 million tons
6 years at brunswick = 365000 x 6 = 2,190,000 or 2.2 million tons
65 more years or 65 x 365,000 tons = 23,725,000, or 24 million tons.

# ASUR PLAN ANALYSIS

## PREPARATION OF ASUR PLAN

**Grp 7-103**

This plan has been developed by Rise Gold, Inc, in response to the comments from the Northern Sierra Air Quality Management District, NSAQMD: "Pursuant to Health and Safety Code section 41511 and the ATCMs (discussed below), the NSAQMD will require that an asbestos sampling plan be developed and approved by the NSAQMD prior to its implementation. It should at least meet the requirements and specifications of ARB Method 435 (see https://ww3.arb.ca.gov/toxics/asbestos/tm435/tm435.htm). This has not been done. No sampling plan has been developed and approved by the NSAQMD." (*Letter between Air Pollution Control Officer of NSAQMD and Matt Kelley, Senior Planner Nevada County, February 10, 2021*)

Rise Gold is listed as the author- no credentialed expert is credited even though they have a PhD Geologist on their team along with several Technical Advisors who are also geologists.

Rise Gold Inc. is incorporated in the state of Nevada. The state of Nevada does not require a license for geologists.

**Grp 7-104**

The sampling plan seems to be derived from "Air Resources Board Method 435, Determination of Asbestos Content of Serpentinite Aggregate (1991)". CARB also published the "*IMPLEMENTATION GUIDANCE DOCUMENT Air Resources Board Test Method 435 Determination of Asbestos Content of Serpentine Aggregate*" in April 2017 to further elucidate the complexities of asbestos testing in an effort to increase consistency and reliability between laboratories. The document states that: "If all parties involved in the collection, processing, and analysis of potential asbestos containing aggregate follow the guidelines specified in this document, more accurate and repeatable M435 asbestos content measurements will result." (*IMPLEMENTATION GUIDANCE DOCUMENT Air Resources Board Test Method 435 Determination of Asbestos Content of Serpentine Aggregate, April 2017, pp i-ii*)

Determine what, if any of these recommendations were implemented

**Grp 7-105**

The sampling and testing will be done by Rise. "Sampling and analytical testing will be done on or off-site by trained and qualified persons under the direction of a State Licensed Geologist" (*ASUR Plan, Item #6, document pg 14 or pg 16 of 131*). Laboratories analyzing asbestos are accredited by NLVAP (National Laboratory Voluntary Accreditation Program). A licensed geologist can work with an Air Pollution Control Officer to identify naturally occurring asbestos (NOA) and create a management plan.

Was the author of the ASUR Plan a California licensed geologist?

So, the parties involved in sampling and testing are not well established as written in the ASUR Plan.

Can the geologist perform testing themselves, train analysts to perform testing or supervise testing? Will any of this work be accepted in a court of law? TBD from a regulatory agency

Mossman is not a licensed Professional Geologist or Certified Engineering Geologist in the state of California. None of the following members of the Rise Gold management team could be found in DCA database for licensure: Thomas Vehrs, Bob Gallagher, Mike Andrews, John Carlile or Alan Edwards (all listed as directors or technical advisors: searches performed under EG-Certified Engineering Geologist, GEO-Professional Geologist, GP-Professional Geophysicist, HG- Certified Hydrogeologist, and MT-Metallurgical Engineer categories). They all have extensive experience in mining, especially international work.

Andrew Kopania (author of the *Groundwater Hydrology and Water Analysis for the Idaho-Maryland Mine Project*) along with Vieira and Kull (NV5 authors of the *GeoTechnical Reports for Centennial and Brunswick Industrial Sites*) were located in the DCA database in order to validate search abilities.

The *Asbestos Sampling Memo (June 2020)* was prepared by Richard Lippoth. He collected the samples from Rise, analyzed the laboratory data and prepared the report. No California licensure is found for him under the Board for Professional Engineers, Land Surveyors and Geologists, DCA.ca.gov He is a one man show at Vergence Geo Services, Inc. with his resume listing work with Freeman-McMoRan and Alexco, a shared history with the Rise management team. His qualification described in the *Asbestos Sampling Memo* June 2020 is listed as geologist, Mr. Richard Lippoth, Reg. SME. SME is a professional organization: the Society for Mining, Metallurgy and Exploration.

## COMPARISON OF PCM TO PLM TO TEM MICROSCOPY TECHNIQUES

Multiple types of microscopy techniques will be used to analyze asbestos content depending on the application of the results. For instance, airborne asbestos monitoring for miners' exposure will use air filtration capture followed by phase contrast microscopy analysis.

**Grp 7-106**

Bulk materials will be screened for asbestos using polarized light microscopy followed by transmission electron microscopy analysis for rolling inventory maintenance.

"TEM is the preferred analytical method for outdoor asbestos samples because of its ability to detect small fibers (greater than or equal to 0.0002 microns in diameter) and to distinguish between asbestos fibers and non-asbestos fibers. The term "TEM structures" is often used to describe asbestos fibers detected by this method. TEM is the method recommended by the California Office of Environmental Health Hazard Assessment (OEHHA). However, TEM measurements cannot be directly related to the cancer potency factors because the studies upon which OEHHA's risk assessment was based used PCM analysis. Thus, the TEM measurements must be converted to PCM-equivalent units (OEHHA 2015.)" (*ASUR Plan, document pp 7 or pp 9 of 131*)

"Asbestos content by TEM structures will be converted into equivalent Phase Contrast Microscopy (PCM) units in accordance with the California Office of Environmental Health Hazard (OEHHA) 2015 Air Toxic Hot Spot Guidance Manual." (*ASUR Plan, Item #3, document pp 8 or pp 10 of 131*)

These different analyses each require unique sampling methods, sample preparation, sample sizes, and microscopy techniques. The results are not directly comparable between the methodologies.

### PHASE CONTRAST MICROSCOPY (PCM)

**Grp 7-107**

"The most common methodology used for asbestos air testing is Phase Contrast Microscopy (PCM). This testing method involves using a PCM microscope to count the fibers present on the cassette filter in order to determine if the total fiber concentration is less than the EPA clearance level of 0.01 fibers/cc (fibers per cubic centimeter) "Asbestos sampling protocol cannot be used for objective data – OSHA." https://www.osha.gov/laws-regs/regulations/standardnumber/1915/1915.1001. Phase contrast microscopy enhances the contrast of transparent materials, while also filtering out background light. The air cassettes used for PCM contain a cellulose ester filter with a pore size of 0.8 um. Once the air sampling is complete, the sample is sent to an accredited laboratory. Alternatively, the samples can be analyzed on-site with a microscope for expediency, but these results will not be accredited. Whether in a lab or on-site, the filter is cut into a pie shape and prepped using a mix of vaporized acetone and triacetin. The sample is then placed on a PCM microscope where the fibers are counted up to 100 fields of view." (www.indoorscience.com, PCM vs TEM Asbestos Air Testing - Indoor Science, March 27, 2018)

Advantages:

2

- Technique is specific for fibers. It is a fiber counting technique which excludes non-fibrous particles from the analysis
- Technique is inexpensive and does not require specialized knowledge to carry out counts
- Analysis is quick and can be performed on-site for rapid determination of air concentrations of asbestos fibers
- Technique has continuity with historical epidemiological studies so that estimates of expected disease can be inferred from long-term determinations of asbestos exposure

Disadvantages:

- Test does not positively identify asbestos fibers. Other fibers may be included unless differential counting is used
- The smallest visible fibers are about 0.2µm in diameter while the finest asbestos fibers may be as small as 0.02 µm in diameter. For some exposures, substantially more fibers may be present than are actually counted.
- Cannot distinguish fibers less than 5 microns in length and 0.25 microns in width

This method is used for airborne fiber determination, not bulk material. It will probably be used for workers' exposure testing. Since OEHHA asbestos risk assessment has used studies involving PCM analysis, TEM results from bulk testing will be converted to PCM equivalent units.

**POLARIZED LIGHT MICROSCOPY (PLM)**

The following method description is excerpted from the Asbestos TEM Laboratories, Inc. cover letter dated Sep/17/2019 found in the *Asbestos Sampling Memo June 2020, pp 26 of 32*: "Sample preparation follows a standard CARB 435 prep method. The entire sample is dried at 135-150 C and then crushed to ~3/8" gravel size using a Bico Chipmunk crusher. If the submitted sample is >1 pint, the sample was split using a 1/2" riffle splitter following ASTM Method C-702-98 to obtain a 1 pint aliquot. The entire 1 pint aliquot, or entire original sample, is then pulverized in a Bico Braun disc pulverizer calibrated to produce a nominal 200 mesh final product. If necessary, additional homogenization steps are undertaken using a 3/8" riffle splitter. Small aliquots are collected from throughout the pulverized material to create three separate microsope slide mounts containing the appropriate refractive index oil. The prepared slides are placed under a polarizing light microscope where standard mineralogical techniques are used to analyze the various materials present, including asbestos. If asbestos is identified and of less than 10% concentration by visual area estimate then an additional five sample mounts are prepared. Quantification of asbestos concentration is obtained using the standard CALARB Method 435 point count protocol. For samples observed to contain visible asbestos of less than 10% concentration, a point counting technique is used with 50 points counted on each of eight sample mounts for a total of 400 points."

**Grp 7-108**

This is a generalized description of the PLM analysis method, actual processes are not documented in the Asbestos Sampling Report June 2020 for the individual samples.

Advantages:

- Basic identifications were first performed by light microscopy so there is a large base of published information against which to check analysis and technique
- Analysis is specific to fibers
- Analysis is quick, requires little prep time and can be performed on-site if equipment is available

Disadvantages:

- Not all fibers present may be seen. This is a problem for very low asbestos concentrations where agglomeration or large bundle of fibers may not be present to allow identification by inference.
- Method requires a great degree of sophistication on the part of microscopist. An analyst is only as useful as his mental catalog of images. Therefore, a microscopist's accuracy is enhanced by experience. The mineralogical training of the analyst is very important. It is the basis on which subjective decisions are made.
- The method uses only a tiny amount of material for analysis. This may lead to sampling bias and false results (high or low). This is especially true if the sample is severely inhomogeneous. (heterogeneity)
- Fibers may be bound in a matrix and not distinguishable as fibers so identification cannot be made

**TRANSMISSION ELECTRON MICROSCOPY (TEM)**

The following method description is excerpted from the Asbestos TEM Laboratories, Inc. cover letter dated Aug/15/2019 found in the *Asbestos Sampling Memo June 2020, pp 21 of 32:* "Sample preparation followed a standard CARB 435 prep method. The entire sample was dried at 135-150 C and then crushed to ~3/8" gravel size. If the submitted sample was >~1 quart, the sample may have been split using a 1/2" splitter following ASTM Method C-702-98 to reduce the sample volume for pulverization. The remaining aliquot, or entire original sample, was then pulverized in a Bico Braun disc pulverizer calibrated to produce a nominal 200 mesh final product. A representative ~60 mg aliquot of material was weighed out, and then placed into solution in a 500 ml beaker filled with distilled water. A known volume of the liquid suspension was filtered onto a 0.2 micron pore size Millipore mixed cellulose ester filter. The filter was then dried in HEPA filtered, Class 100 air on a clean bench. The filter was placed onto a glass microscope slide, sectioned, and collapsed in acetone. The collapsed filter was plasma-etched to remove10% of the filter surface and then carbon coated. The carbon coated filter was sectioned

**Grp 7-109**

3

and the sections placed onto 200-mesh copper TEM sample grids in dimethyl sulfoxide and acetone wick washers. After sufficient time to dissolve the filter material, the TEM sample grids were removed from the baths and placed into labeled sample containers.

TEM analysis was performed on a Philips CM-12 or JEOL 1200 transmission electron microscope operating at 80 or 100 kV. The sample was placed into the microscope where it was first scanned at low magnification to confirm that the distribution of material was reasonably homogeneous. High magnification analysis was performed using a two tier approach: 1) A relatively large area of several TEM grid openings for large asbestos fibers or fiber bundles, and 2) a relatively small area of a number of fields of view for individual asbestos fibers (fibrous particles exhibiting an aspect ratio greater than or equal to 3 to 1, and a length greater than or equal to .5 um). Detected asbestiform structures were subjected to detailed morphological and/or selected area diffraction analysis. If necessary, energy dispersive X-ray analysis was also performed. The length and width of each asbestos fiber was measured. From this data, a total volume and mass of asbestos observed in the scanned area is calculated, and extrapolated to a total weight percent asbestos for each sample."

At the top of the same letter is the statement: "Please find below the results for the TEM analysis of one or more bulk material samples. The analytical procedures were performed according to the EPA Test Method For the Determination of Asbestos in Bulk Building Materials - TEM method (EPA 600/R-93/116) modified for quantitative bulk soil sample analysis."

How was this method for bulk building materials modified for bulk soil sample analysis? These are rock cores.

In these analyses, an ~60 mg sample was suspended in 500 ml distilled water. Then a 0.5 ml aliquot was filtered for analysis. While TEM can identify fibers too small to be seen with PLM, the sample size is reduced by order of magnitude, $10^{-6}$.

"Samples are first analyzed using PLM because a much larger (and likely more representative) mass of sample powder is analyzed using PLM than when using TEM. The mass of a M435 sample analyzed by PLM is approximately one million times greater than the mass of a TEM sample, but TEM has a resolving power of 500 to 20,000X magnification (compared to 50 to 1000X magnification by PLM). This higher resolving power enables TEM microscopists to distinguish and identify finer particles and fibers not seen with the use of PLM. For example, the California Department of Toxic Substances Control has used PLM, followed by TEM, as part of a tiered analytical approach to verify the absence of asbestos fibers determined by M435 PLM analyses in its Schools Program." (*IMPLEMENTATION GUIDANCE DOCUMENT Air Resources Board Test Method 435 Determination of Asbestos Content of Serpentine Aggregate, April 2017 pp 23-24*)

**Grp 7-110**

This is a "potential" quantity of mass available for analysis by PLM vs TEM, not the actual mass analyzed.

Advantages:

- Fibers can be accurately identified-ability to distinguish between asbestos and non-asbestos fibers
- Small fibers can be detected

Disadvantages:

- High resolution may be selective for a specific size fiber and exclude others
- Actual amount of material examined is magnitudes less than quantity examined by PLM
- Sample heterogeneity impacts overall representativeness

Bottom line is that these methods are not comparable due to differences in sample preparation and microscopy techniques. These analyses contain inherent bias due to sample variability (lack of homogeneity), differences in sample quantities tested, magnification levels and individual microscopists' expertise.

COMPARISON OF RESULTS FROM ASBESTOS SAMPLING MEMO (June 2020) TO ASUR PLAN TEM RE-TEST (Nov 2021).

**Grp 7-111**

For the 42 samples analyzed during August and September 2019, asbestos was detected in 4 samples, 9.5% of total samples. This included two blanks, two Centennial site tailings and 38 rock core samples. Two samples were analyzed by TEM and the remaining 40 samples by PLM. Asbestos was found in the two TEM samples and two of the PLM samples.

"In 2021, Rise requested the 40 samples previously submitted to be reanalyzed using the TEM method." (*ASUR Plan, document pp 7 or pp 9 of 131*).

Actually, the TEM reanalyses were performed at the urging of the air district: ["As the NSAQMD wrote in its July 10, 2020 comments "The NSAQMD recommends additional TEM analyses of the above rock types (serpentinite, weakly ankeritized diabase/serpentinite, weakly ankeritized serpentinite and ankeritized serpentinite) in order to facilitate refinement of the preliminary risk assessment". The NSAQMD still sticks to this recommendation"]. (Letter between Air Pollution Control Officer of NSAQMD and Matt Kelley, Senior Planner Nevada County, February 10, 2021)

In retesting of the 40 samples (two tailings and 38 pulp samples) analyzed by TEM, asbestos was detected in 14 samples. Unfortunately, the August 2019 samples tested by TEM were not retested by TEM in 2021. Thus, there is no quality control data regarding variability and reproducibility of results regarding TEM analysis between those two samples. The following chart is a comparison of asbestos found by TEM vs PLM. Detection limit for PLM is 0.25 weight% and the detection limit for TEM is 0.001 weight %. Non-detect samples from TEM re-testing have been excluded.

4

| Sample Number | Date Reported | PLM Result weight % Detection Limit 0.25 | TEM Result weight % Detection Limit 0.001 | % Difference PLM vs TEM | Location and sample drill core length (inch) | PCM equivalent units weight % |

| | Nov 10, 2021 | | 0.01 | | 4.8 | 0.038 |

Overall, 16 samples, 40%, had asbestos greater than the TEM detection limit of 0.001 weight %.

Eight of the 40 samples, 20%, had asbestos >0.01 PCM equivalent units Weight %.

NOTE: sample Y962994 had a TEM result of 0.13 weight % yet zero result for PCM equivalent units. Data was notated: "Actinolite asbestos detected. Concentration per Millions of Fibers per gram: 29 for fibers >5µm in length. Possible contamination." This same situation occurs for samples Y962828, Y962833, Y962835, Y962836 and Y962843.

Two samples for TEM analysis originally sent to the laboratory on Aug 8, 2019 were described as rock cores with date analyzed as Aug 15, 2019. The 40 samples for PLM analysis were described as rock cores and were originally sent to the laboratory on Sept 3, 2019 with date analyzed as Sept 17, 2019. For retesting, 40 samples described as pulverized rock were submitted to the laboratory on Sept 14, 2021 with date analyzed as Nov 10, 2021. The two samples originally tested by TEM, Y962980 and Y962981, were not retested in November 2021. All of these samples were stored somewhere for two years before being retested. The actual age of the samples is unknown since drill core logs are not available. Rise performed exploratory drilling between 2017-2019.

SAMPLE POPULATIONS

**Grp 7-112**

Not counting the two grab tailings samples from the Centennial Site and the two blanks (carbonate landscape rock), the average overall length of the sample cores tested was 5.34 inches. Samples were from 6 of 19 (32%) of total cores drilled by Rise: 9 samples from I-18-11, 1 sample from I-18-12, 9 samples from I-19-13, 7 samples from I-19-13A, 8 samples from I-19-14 and 4 samples from I-19-14A. Drilling was stopped when asbestos was detected. Drill logs are not available; therefore, it is impossible to determine the depth or width of serpentinite deposits encountered. Asbestos sampling was extremely limited. Centennial tailings were only identified by a grid number-no information as to quantity, location, depth, etc. There are labeling errors: 1) *Asbestos Sampling Memo June 2020, Appendix A*- First photo is mislabeled Y962880 instead of the correct label Y962980 and 2) sample Y962838 is located on drill hole I-19-12 on Sheet 2

5

Mine Geology and Asbestos Samples (*Asbestos Sampling Memo June 2020*) but is listed as being from drill hole I-18-12 in the *ASUR Plan, Appendix C, pp 55 of 131.*

DUPLICATE ANALYSIS

Y962847 and Y962981 are duplicate samples. How does a result of 0.44 TEM weight % and 2.0 TEM weight % calculate out to the same PCM equivalent unit result of 0.028 weight%? (*ASUR Plan, Appendix C, document pp 57 of 131*)

These two separate samples Y962981 and Y962847 were quality control duplicates. These were two different samples, Y962981 was initially received as a rock core sample and was only analyzed by TEM on 8.15.19. The results yielded 22 chrysotile structures <5µm and 17 structures ≥ 5µm with a calculated asbestos concentration (weight %) of 2.0 (*Asbestos Sampling Memo, June 2020, Appendix B, pp 23 of 32*).

The duplicate sample, Y962847 was initially received as a pulps sample and was tested by PLM on 9.3.19 with <0.25% result. This sample was retested by TEM on 11.10.2021 and yielded 233 chrysotile structures <5µm and 10 structures ≥ 5µm with a calculated asbestos concentration (weight %) of 0.44 (*ASUR Plan, Appendix B for Asbestos TEM Laboratories Report, pp 110 of 131*).

**Grp 7-113**

Yet, the ASUR Plan lists these results as identical with the same Structures/nanogram at 3.0 and the same PCM Weight % at 0.028% (*ASUR Plan, Appendix C, pp 57 of 131*)

The weights used for sample preparation are 62.5 mg for Y962981 and 58.9 mg for 962847, a difference of 5.9%. But the difference in calculated asbestos weight concentration is 128%. Sample Y962847 has more than 10 times the number of chrysotile structures.

A 6% lower weight yields a 10 times higher structure count but the same PCM equivalent units????

Only one of these samples was included in the four total samples used to calculate the content in serpentinite samples. Which one? Who picks which one? Can the quality control sample, as a separate sample, be excluded from the analyses? (*ASUR Plan, Appendix C, pp 57 of 131*)

Comparing the results for the duplicate sample, Y962847, by TEM analysis yields 0.44% by weight compared to sample, Y962981 at 2.0% by weight, again yielding a 128% difference. Even using the same analytical test procedure (TEM analysis) yields unsatisfactory QC results.

NOTE: The only definitive conclusion from all of the asbestos testing is that:
asbestos was found in all of the serpentinite samples in addition to being found in samples of weakly ankeritized diabase/serpentinite, weakly ankeritized serpentinite, diabase and porphyrite at levels >0.01% PCM equivalent units (*ASUR Plan, Appendix C, pp 55-57 of 131*).

Grouping the samples by lithology in an effort to dilute the overall asbestos content of the group does not negate the asbestos content of the individual sample and its potential for harm. (*ASUR Plan, Appendix C, pp 54 of 131*)

QUALITY CONTROL ISSUES

The laboratory report for retesting of 40 sample by Asbestos TEM Laboratories, Inc. is labelled Report NO. 375516 rev.1

Why was the report revised? Where is the original for comparison?

**Grp 7-114**

Per documentation provided, no blind blanks or blind duplicates were performed. No documented cross check verifications from second analyst or second microscope were performed on individual samples. Two analysts performed the 40 sample TEM re-tests. The first analyst tested the first 18 samples, followed by the second analyst for next 13 samples, first analyst again for one sample, second analyst for remaining 8 samples. No time stamp for each sample, thus unable to determine if samples were analyzed in the order listed according to laboratory sample ID.

Two of the TEM samples had grid opening damage, Y962984 and Y962988.

Eight of the 40 samples were notated as having "possible contamination" with two types of contamination listed, chrysotile for two samples and actinolite for 6 samples. Twenty percent of the samples had "possible contamination", 5% by chrysotile and 15% by actinolite.

TOXICITY

**Grp 7-115**

CHRYSOTILE VS AMPHIBOLE ASBESTOS

What if these samples did not have "possible contamination" but contained actual naturally occurring actinolite (amphibole) asbestos?

6

Upon retesting by TEM, ten samples (25%) indicated amphibole asbestos which has a much higher cancer potency than chrysotile asbestos.

Particularly controversial is the question of whether chrysotile asbestos is less potent for the induction of lung cancer than the amphibole forms of asbestos (e.g. crocidolite, amosite and tremolite), which has sometimes been referred to as the "amphibole hypothesis" (Cullen, 1996; Stayner et al., 1996; McDonald, 1998). This argument is based on the observation from experimental studies that chrysotile asbestos is less biopersistent (i.e. has a shorter half life) in the lung than the amphiboles... [The Working Group noted that the lower biopersistence of chrysotile in the lung does not necessarily imply that it would be less potent than amphiboles for lung cancer.] https://www.ncbi.nlm.nih.gov/books/NBK304374/

"The amphiboles are more likely to be associated with mesothelioma than is chrysotile, or white asbestos, which has a two to four times less potent risk of mesothelioma: however, the risk for development of lung cancer is equipotent for all types of asbestos. Chrysotile accounts for more than 99% of the world production of asbestos and commonly is contaminated with tremolite and other asbestos fibers." (Walker MD, Christopher, Pleural Neoplasms, Muller's Imaging of the Chest, 2019 Retrieved from ScienceDirect.com 02.22.2022)

POTENTIALLY TOXIC ELEMENTS

Potentially toxic elements (PTEs) hosted in asbestos elongate mineral particles is one of the factors that determines their toxic/pathogenic effects. Metals such as Fe, Mn, Cr, and Be are known to induce toxicity and contribute to asbestos related diseases. "...it is essential to quantify the toxic elements present in asbestos elongate mineral particles in order to prevent asbestos-related diseases." https://doi.org/10.1016/j.chemgeo.2020.119896

**Grp 7-116**

"Iron ions on amphibole types of asbestos react with epithelial lining fluid in the lung and generate reactive oxygen species that induce toxicity, and oxidant stress may lead to DNA damage. There is a direct relationship between biopersistence, which is determined by fiber length and chemical composition, and toxicity. Longer, thinner fibers are more toxic because they are not cleared by the AMs and therefore persist in the lung. Fibers longer than 15μm are particularly toxic and bioactive. They are not completely engulfed by the macrophages, leading to release of lysosomal contents, cytotoxicity, oxidant stress, and stimulation of inflammatory and growth factor pathways." (Harkema...Haschek, Fundamentals of Toxicologic Pathology, Chapter 14-Respiratory System (Third Edition), 2018 pp 351-393. Retrieved from ScienceDirect 02.22.2022 https://doi.org/10.1016/B978-012-809841-7.00014-9)

Many of these samples have high metals content, especially iron. Chart this

The data used for heavy metal toxic air contaminants in the Health Risk Assessment are all notated by the laboratory as being received and tested beyond the EPA recommended hold times of 28 days for mercury and 6 months for all remaining metals. Exploratory drilling began in 2017. Since the drill logs are unavailable, the exact sample dates for each core are unknown, but all samples were submitted and received by the gold assay laboratory on February 20, 2019. (Inorganic Extended Qualifier Reports pp. 389-407 and 458-484, Appendix D, Groundwater, Hydrology and Water Quality Analysis Report-Appendices)

**Grp 7-117**

After assays were performed, samples were then submitted to ACZ Laboratories for metal analyses. These analyses were performed in November 2019. This means that all samples were tested at least 9 months beyond their expiration date, probably more.

Shouldn't valid data be used when evaluating the health risks to the community from these TACs, especially when these metals have to ability to potentiate the effects of asbestos?

MATERIAL SAMPLING LOGISTICS

"The sampling will be done from the transfer point between the skip and silo and may be taken either manually or with an automated sampler." Illustrated by Figure 2 (*ASUR Plan, document pp 14 or pp 16 of 131*)

**Grp 7-118**

According to correspondence between the Air Pollution Control Officer of NSAQMD and Matt Kelley, Senior Planner of Nevada County on February 10, 2021, the APCO states: "A key component of method 435 is the protocol for collecting representative samples. It is improper to simply pull out the laboratory portion of Method 435 and say that Method 435 is being used. Method 435 states, "1.2 Applicability. This method is applicable to determining asbestos content of serpentine aggregate in storage piles, on conveyor belts, and on surfaces such as roads, shoulders and parking lots." Then it specifies even more clearly, "3 APPLICABLE SOURCES. This method can be used to obtain bulk material sources from three types of sources: 1. Serpentine aggregate storage piles. 2. Serpentine aggregate conveyor belts 3. Serpentine aggregate covered surfaces...In aggregate, a large degree of homogeneity has already been achieved during the aggregate's production."

Does pulling samples at the skip drop point into the silo meet the above stipulated criteria for Method 435 sampling, does this method qualify as a conveyor belt?

**Grp 7-119**

Who would be in the silo at point 3 in diagram as shown on document pp 14. (*ASUR Plan*) to obtain a sample manually?

**Grp 7-120**

"It is recommended that sampling be done at point closest to end of processing." (*IMPLEMENTATION GUIDANCE DOCUMENT Air Resources Board Test Method 435 Determination of Asbestos Content of Serpentine Aggregate, pg ii*).

7

This point in the silo may be adequate for barren rock samples but not tailings samples comprised of ore rock regarding the "point closest to end of processing," as stated above.

What will be the timing/spacing of the individual 3 samples taken for each composite per 1000 tons? Beginning, middle, end or every 333 tons? Beginning and end sampling method would mean that samples would overlap (beginning, end) and (end, beginning) samples per 1000 tons. Weighting sampling at these points would not be representative of the entire batches.

Will barren rock and ore rock be analyzed separately or combined in a composite (3 samples will be composited per 1000 tons of rock each day (*ASUR Plan, document pp 13 or 15 of 131*)? If barren rock and ore rock are to be placed in different compartments of the concrete silo, how will you be able to determine which material is contaminated, if asbestos content >0.01% PCM equivalent units is later found in the rolling inventory?

**Grp 7-121**

The concrete silo is divided into three compartments, one 1000 tons area and two 400 tons containment areas. The ore rock would flow through the larger compartment and then be conveyed to the ore processing plant for pulverization into tailings, while the barren rock would be loaded into haul trucks for transport.

How would you determine if the contaminated material was from the ore rock or the barren rock if the composited sample contains both materials? Rise would have to assume that all material from last non-detect test (per 1000 tons batch) to the next non-detect test (per 1000 tons batch) is contaminated.

Using a weighted average taken over three months of 1000 tons per day ore rock (90,000 tons) and 500 tons per day barren rock (45,000 tons) allows for significant dilution of asbestos per batch. Will an individual batch that fails TEM analysis be allowed to remain among the passing TEM analyses batches?

## ROLLING INVENTORY MAINTENANCE LOGISTICS

Pg 13 (pp 15 of 131), ASUR Plan item 4: "Analytical determination of a materials status as Asbestos Containing Material would be done using Polarized Light Microscopy (PLM) in accordance with ARB Method 435 pursuant to 17 CCR 93106 (h)(2) with a detection limit of 0.25% asbestos"

Pg 13 (pp 15 of 131), ASUR Plan item 5: "Analytical determination of asbestos content, for the purposes of maintaining an Asbestos Inventory, would be done using Transmission Electron Microscopy (TEM) method in accordance with the EPA/600/R-93/116 method. Sampling for the Asbestos Inventory would be done by compositing at least 3 random grab samples from the barren rock or sand tailings for every 1000 tons of material."

**Grp 7-122**

But on page 8 (pp 10 of 131) of the ASUR Plan are the statements:

4) An Asbestos Inventory of all mined materials will be maintained and include a 3-month rolling average of asbestos content in equivalent PCM units.

5) An Engineered Fill Placement Plan will be maintained to ensure that adequate non-Asbestos Containing Material, as determined by PLM testing, is available for Surfacing Applications.

If all mined material is tested by TEM and converted to PCM equivalent units, then how can Rise maintain an Engineered Fill Placement Plan based just on PLM testing? There is no comparison or conversion factors of PLM measurements to TEM measurements. (Only TEM measurements are used to convert to PCM equivalent units)

"A rolling three-month weighted average of asbestos content of mined materials brought to surface and materials used as Engineered Fill will be maintained in the Asbestos Inventory. (*ASUR Plan, document pp 15 or 17 of 131*)."

"Arrangements will be made to ensure that analytical data is received and entered into the inventory within 2 weeks of sampling" (*ASUR Plan, pp 15 or 17 of 131*)

**Grp 7-123**

Will a new weighted average be calculated with each 1000 tons of material added to the inventory? WHERE WILL THIS MATERIAL BE STORED? WILL 1000 TON INDIVIDUAL BATCHES OF ORE ROCK ALONG WITH 500 TONS INDIVIDUAL BATCHES OF BARREN ROCK BE MAINTAINED? HOW MUCH MINING WILL BE PERFORMED DURING THAT TWO WEEKS OF TURN AROUND TIME? HOW WILL THE AMOUNT OF "POSSIBLY CONTAMINATED" MATERIAL BE DETERMINED?

For example, Y962847, would have initially passed the screening PLM method of testing. However, the material would have failed when tested by TEM during rolling inventory. Material surrounding this sample in the 90-day rolling inventory would be unfit for engineered fill or aggregate transport.

8

WILL THE SAME SAMPLE ANALYZED BY PLM BE RE-TESTED USING TEM OR WILL RANDOM SAMPLES FOR EACH TEST (PLM and TEM) BE UTILIZED?

FUGITIVE DUST EMISSIONS ABOVEGROUND

**Grp 7-124**

The 3-month rolling inventory will consist of 1000 tons of tailings for engineered fill per day multiplied by 90 days equals 90,000 tons plus 500 tons of barren rock for engineered fill per day multiplied by 90 days equals another 45,000 tons. 500 tons of tailings will be deposited underground in CPB.

How will the 500 tons designated for CPB be determined? How will this material be culled from the rolling inventory? (Assuming that any tailings containing asbestos would be the most suitable for underground CPB placement)

**Grp 7-125**

Where will this 135,000 tons of materials be stored and how will it be loaded for transport to Centennial, Brunswick or outside vendors? Have the fugitive dust emissions for the storage and loading been calculated and included in PM emissions analysis and incorporated into Health Risk Assessment model?

**Grp 7-126**

The Air Quality Report calculates emissions based on loading from an enclosed area: "Barren rock will be transported from the concrete silo using a series of chutes and conveyors to a fully enclosed truck loading building." (*Air Quality and Greenhouse Gas Emissions Analysis, Appendix B, Health Risk Assessment, Earthwork and Material Handling Nov 2021, document pp 24*) This statement does not account for rolling inventory procedures.

**Grp 7-127**

On document page 35, *Noise and Vibration Report, Rock Bin Conveyors and Barren Rock Loading* is the statement:
"The existing concrete rock silo will be reused. A chute and conveyor system will transfer barren rock from the silo into trucks for transport as engineered fill. The conveyor system and truck loading area will be inside a building adjacent to the headframe. A chute and covered conveyor system, approximately 335 feet long, will transfer gold mineralization from the silo to the process plant."

On document page 11, *Centennial GeoTechnical Report*: "The conveyor system and truck loading area will be inside a small building adjacent to the headframe."

On document page 14, *Centennial GeoTechnical Report, Table 4, Buildings* lists the Rock Truck Loading building as 1700 square feet with a maximum height of 20 feet.

Is the building large enough to accommodate the 45,000 tons of barren rock rolling inventory and room for front-end loading into haul trucks from that inventory? What is the ventilation system for this building?

**Grp 7-128**

On document page 36 *Noise and Vibration Report, Process Plant* is the statement:
"Gold mineralization hoisted from the Brunswick shaft will be placed in the existing concrete silo located on the Brunswick property before processing begins. Gold material will be transported from the concrete silo using chutes and conveyors to a fully enclosed process plant....Sand tailings (waste) from the gold recovery process will be dewatered and used for either backfill for the underground mine or stockpiled for transport and use as engineered fill. Sand tailing during backfilling will be transferred to the paste backfill plant, where particles will be dewatered and mixed with cement into a paste....Sand tailings not used for backfill will be either directly loaded into trucks in the process plant or stockpiled inside the building. Stockpiled sand tailings will be loaded into transport trucks with a front-end loader during daytime hours. Sand tailings not used as underground backfill will be transported for use as engineered fill."

(Document pp 39, *Noise and Vibration Report, Table 9 Hours of Operation*):
"Outside Truck Loading by Loader 7:00 AM-7:00 PM, 7 Days a Week, 80 years"

(Document pp 17, *Applicants Project Description, Table 7, Hours of Operation*):
"Outside Truck Loading by Loader 7:00 AM-7:00 PM, 7 Days a Week, 80 years"
This is confirmation of "outside loading" across documents.

Will this loading occur inside or outside? Will it be stockpiled inside or outside? If these procedures change due to maintenance of rolling inventory storage: will noise levels increase, will amounts of fugitive dust increase? What is the potential for all equipment and storage areas to be contaminated with asbestos? What level of asbestos found by TEM testing in the 90 day rolling inventory will trigger decontamination of all equipment: conveyor belts, processing plant, cement plant, etc.?

**Grp 7-129**

Will these two components of the engineered fill be kept separate? Otherwise, how will the engineering firm determine correct ratios for mixing to ensure stability upon engineered fill placement?

Recommendations from NV5:
"2. Crushed blast rock with a maximum dimension of 6 inches may be blended into the sand tailings to produce engineered fill material at a ratio of up to 2 parts blast rock to 1 part sand tailings. A rock and sand ration greater than 2:1 may be feasible but would not likely be testable using nuclear methods.
4. Onsite blending of blast rock and sand tailings may be performed by earthwork equipment (e.g., windrowing and spreading the rock and sand together in thin lifts). Specific procedures for onsite blending should be developed in conjunction with an NV5 representative during initial fill placement." *Centennial GeoTechnical Report*, document pp 13

9

Document pp 16. *Centennial GeoTechnical Report*: "Engineered fill may be mixed on site using mobile equipment to ensure uniformity and meet specifications for compaction."

FUGITIVE DUST EMISSIONS UNDERGROUND

**Grp 7-130** "The walls and roof of tunnels composed of rock containing significant asbestos will be covered with shotcrete and the floor with be covered with either concrete or 3 inches of non-Asbestos Containing Material. Shotcreting would be done as part of the tunneling cycle or after completion of tunneling. Floor covering would be done after completion of tunneling (*ASUR Plan, document pg 10 or pp 12 of 131*)."

How much cement does this add to mine operations and subsequent GHGs? Hexavalent chromium deposition? What level of asbestos is considered significant to warrant shotcrete?

**Grp 7-131** DEIR pg 3-38 Lists a "Shotcrete Machine" that will "Spray concrete into the walls of the galleries to prevent rockfall." Is shotcrete to be used on all tunnels and not just significant asbestos areas?

"Water generated from drilling and dust suppression during tunneling in Asbestos Containing Material shall be collected in sumps or tanks and shall not be used for Surfacing." (*ASUR Plan, document pp 11 or pp 13 of 131*)

**Grp 7-132** (*ASUR Plan, document pp 12 or pp 14 of 131*): "#6. Rock loads will be wetted for transit between the tunnelling and dumping area and equipment will be washed regularly to prevent dust from being tracked out into other areas of the mine."

How will this water be treated to remove asbestos? What will be the volume of asbestos contaminated water?

MERV 16 filters will remove 95% of fibers...that still leaves 5 % ... Rise claims that only 1% of material mined will be serpentinite.

Will MERV 16 filters be limited to serpentinite mining only? What type of filters will be utilized in main ventilation system? What is the quantity of asbestos in the 5% of what total mined quantity of serpentine/serpentinite?

**Grp 7-133** The *Air Quality and Greenhouse Gas Emissions Analysis Technical Report: Earthwork and Material Handling Fugitive Dust: Construction Activity Fugitive Dust Nov 2021 pp 300* of 1938 states that the Serpentinite Content of Mine Fill will be 14.3% with an Asbestos content of serpentinite at 0.20%.

The final total is 0.03% (14.3% x 0.20% = 2.86% ÷ 100 = 0.03%) ???????

HOW CAN THE MINE FILL BE 14.3% SERPENTINITE IF ONLY 1% OF MINED MATERIAL IS SERPENTINITE?

ENFORCEMENT OF ROLLING INVENTORY ASBESTOS CONTENT

"If the three-month rolling Asbestos Inventory for materials hoisted to the surface exceeds 0.01% asbestos by mass of PCM equivalent units the geology department will immediately investigate the source of the asbestos containing material and halt mining in the area of concern until a revised mine plan is prepared in compliance with the ASUR Plan (*ASUR Plan, document pp 20 or pp 22 of 131*)."

**Grp 7-134** Document page 9, ASUR Plan needs further interpretation/clarification:

"If planned mining is projected to result in the Asbestos Inventory 3-month rolling average to exceed 0.01% by mass equivalent PCM units (1.07 TEM structures per nanogram)

i. Gold mineralization (intended for processing) will <u>not</u> be mined
ii. Barren rock from tunneling will either not be mined or mined using an auxiliary ventilation and dust collection system, as described in Section 6.1, designed to capture dust generated during the mining of these materials and prevent this dust from entering the main ventilation system and exhausting from the underground mine and a location for the underground disposal of this material will be specified and annotated on mine development plans."

SO, IF YOU ARE NOT GOING TO REMOVE THE GOLD MINERALIZATION, WHY WOULD YOU REMOVE THE BARREN ROCK SURROUNDING IT?

(*ASUR Plan, document pp 14 or pp 16 of 131*): "Records of all analytical testwork conducted will be retained for the life of the operation or a minimum of 7 years."

**Grp 7-135** Once in the environment, asbestos does not degrade and will continuously be released into ambient air by wind or any soil disturbance.

Worker exposure occurs only during employment hours; however, community exposure occurs 24 hours per day. Workers choose to work in this environment with financial compensation. Workers are also provided training, respiratory protection, monitoring and health benefits while the community has none of these advantages.

10

The life of the operation or 7 years of record retention is not an adequate retention period since disease caused by exposure may not manifest for 20 years-these are human lives at stake NOT TAXES!

DUE TO IMPLICATIONS FROM LONG TERM EXPOSURE TO ASBESTOS, RECORDS OF ALL ANALYTICAL TESTWORK MUST BE RETAINED INDEFINITELY.

(*ASUR Plan, document pp 19 or 21 of 131*): #10; If required by the NSAQMD, the plan must include an air monitoring component."

(*ASUR Plan, document pp 20 or pp 22 of 131*): "A geological report will be prepared annually with a summary of all materials mined. The report will include a summary of quantities of rock mined by lithology. The report will include analytical asbestos sampling data and all receipts issued for Engineered Fill. The report will include any dust sampling taken during operations. The report will include the results of any air monitoring or asbestos bulk sampling conducted at the request of NSAQMD."

**Grp 7-136**

A team of third-party licensed geologists should be monitoring and recording the above data every day to be utilized for reporting. The majority of this work is being performed underground...who will know the difference after the material is extracted, crushed and placed as engineered fill or hauled away?

BESIDES A REPORT, WHAT ACTIONS WILL BE TAKEN? ARE THERE ANY PENALTIES FOR EXCEEDENCES?

Is this plan legally enforceable? What if Rise obtains all the necessary permits to begin mining and decides to sell those permits to a third party or what if Rise sells the mine itself to a third party in the future...will the plan be required for the new operator?

Rise has stated that they will leave the infrastructure at the Brunswick site.

What assurances does the county have that the infrastructure will be clean and free from asbestos, heavy metals and silica contamination?

## CONCLUSIONS:

The addition of the 3-month rolling inventory complicates downstream processes tremendously. It has the potential to affect air quality through increased fugitive dust emissions which increase the quantities of the TACs (asbestos, silica and heavy metals) being released directly impacting the Health Risk Assessment results. The health of the community is at stake.

**Grp 7-137**

Asbestos emissions are now being calculated on the assumption that rock material will contain 0.01% asbestos as described by the ASUR Plan. However, the ASUR Plan cannot control the actual asbestos content in the material being mined, the plan can only try to control the distribution of material being used for engineered fill to a 0.01% asbestos content. The actual asbestos content of rock being mined is unknown and highly variable.

CAN YOU ASSUME THAT ALL MATERIAL (BARREN ROCK AND ORE ROCK) WILL BE ONLY 0.01% ASBESTOS WHEN CALCULATING EMISSIONS?

CLASSIFICATION AND QUANTIFICATION IS NOT POSSIBLE UNTIL AFTER TESTING BY TEM OCCURS, AND THAT INFORMATION MAY NOT BE KNOWN UNTIL TWO WEEKS AFTER EXTRACTION AND TRANSPORT TO THE SURFACE.

"The average asbestos content of the total mined material is of primary concern since asbestos does not have established acute noncancer effects (OEHHA 2020). Therefore, only the average asbestos emissions that could be generated over the long-term (per year), and associated long-term health risk, has been evaluated herein." (*Air Quality and Greenhouse Gas Emissions Analysis Nov 2021, document pp 36*) Rise now estimates these emissions at 0.01%.

This is the same logic regarding acute vs long term exposure for the community. "Asbestos is classified as a known human carcinogen by the US state, federal, and international agencies, as well as by the World Health Organization" (Walker). There is no safe level of asbestos exposure (*WHO*).

ANY asbestos released to the ambient environment regardless of an immediate quantity released has the potential for long term implications because asbestos does not readily degrade once in the environment. "It is one of the most pervasive environmental hazards in the world. (Walker) "We know very little about the rates of weathering and leaching of asbestos in soil environments, but the available information suggests that substantial reductions in the amount of chrysotile may take hundreds or thousands of years, depending on the soil environment, and somewhat longer for amphibole asbestos." (*GUIDELINES FOR GEOLOGIC INVESTIGATIONS OF NATURALLY OCCURRING ASBESTOS IN CALIFORNIA, Special Publication 124, 2002 pp 24*)

HEALTH RISK ASSESSMENT CRITIQUE:

Community Health Risks from Exposure to Toxic Air Contaminants

**Grp 7-138**

"As explained in Section 2.1.2.2, Non-Criteria Air Pollutants, of the AQ-GHG Technical Report, a TAC is an air pollutant, identified in regulation by CARB, which may cause or contribute to an increase in deaths or serious illness, or which may pose a present or potential hazard to human health...Health effects to TACs may occur at extremely low levels and it is typically difficult to identify levels of exposure which do not produce adverse health effects. "(*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B Memorandum, Subject: Idaho-Maryland Mine-Health Effects from Criteria Air Pollutants, pg 10, 2021*)

"A dispersion modeling analysis was conducted for DPM emitted from diesel vehicles and off-road equipment, blasting emissions, as well as for TACs from fugitive dust sources on the proposed project site for the HRA to assess the health risk impacts of the project's construction and operation on proximate off-site sensitive receptors." (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 8, 2021*) "The cancer risk calculations were performed by multiplying the predicted dispersion modeled output data by the TAC emissions and the appropriate risk values...The noncancer health impact of an inhaled TAC is measured by the hazard quotient, which is the ratio of the ambient concentration of a TAC in units of µg/m3 divided by the reference exposure level (REL), also in units of µg/m3." (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 4, 2021*)

"For evaluating health risk, the HRA was based on the assumption that exposure from construction and operational TAC emissions would generally occur up to 20 hours per day, 7 days per week for construction and up to 24 hours per day, 7 days per week, for 30 years for operation. This is consistent with OEHHA's guidance for performing operational HRAs.1" *(Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 1, 2021)*

The Idaho-Maryland Mine Project permit is for 80 years, almost three times the 30 years of exposure used in the health risk assessment.

WHAT WILL BE THE IMPACT ON HEALTH AFTER THOSE 30 YEARS OF EXPOSURE AND BEYOND?

1

This critique will examine input data points used in the AERMOD dispersion model whose output data then predicts the health risk impacts to the community from exposure to toxic air contaminants.

AERMOD MODEL

Regarding the selected dispersion model and its inputs is the statement -"Principal parameters of AERMOD for the project operations included the following:

- Dispersion Model
- Meteorological Data
- Urban and Rural Options
- Terrain Characteristics
- Sensitive Receptors
- Source Release Scenario
- Buildings" (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pp 8-12, 2021*)

Several of these principal parameters require additional scrutiny with regards to the actual inputs used in the model and their applicability to the Grass Valley community in terms of future health risks.

**Grp 7-139**

Air pollutant dispersal is dependent on several factors: wind speed, wind direction, atmospheric stability and topography. (Transport and Dispersion of Air Pollution, Chapter 3, www.3epa.gov)

Atmospheric stability is dependent on the forces that relate to the vertical movement of air such as air density, air pressure, temperature and relative humidity. These forces dynamically interact on a constant basis to affect turbulence and the subsequent dispersal patterns of pollutants. It becomes critical to obtain the most accurate meteorological data available for input into these models which then estimate the health risks for cancer along with acute and long-term illness from exposures.

METEOROLOGICAL DATA

From the EPA Support Center for Regulatory Atmospheric Modeling (SCRAM) Air Modeling-Observational Meteorological Data: "Observed meteorological data for use in air quality modeling consist of physical parameters that are measured directly by instrumentation and include temperature, dew point, wind direction, wind speed, cloud cover, cloud layer(s), ceiling height, visibility, current weather, and precipitation amounts. These data are used in air quality models to capture the atmospheric conditions occurring at a source and/or receptor location, and therefore, play an important role as they effect the concentration of pollutants at receptors of interest." (www.epa.gov/scram/air-modeling-observational-meteorological-data, retrieved 1.27.2022)

The HRA states: "The nearest stations with processed meteorological data for use in AERMOD are Blue Canyon (17 miles away), Auburn (18 miles away) and Beale (22 miles away). The predominant wind direction at the project site is from the North-East and South-West direction (Meteoblue 2020). The Blue Canyon met station has a predominant wind direction from the North-East and South; the Auburn met station from the East; and the Beale station from the South-East and North-West (CARB 2020)." (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 12*)

"Blue Canyon was selected since it is the closest station and is the most representative of the project site. "(*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk*

2

*Assessment, Appendix B, pg 12, 2021*) There are multiple reasons why Blue Canyon is NOT representative of the project site in terms of meteorological conditions.

Blue Canyon is in the Sierra Nevada Mountains at an elevation of 4695 ft. This elevation creates a very different climate and weather patterns than what Grass Valley experiences in the foothills at an elevation of 2411 ft. Simply changing the terrain elevation data input does NOT correct for the differences in air density, air pressure, solar heating and dry/wet adiabetic lapse rates that result from the significant disparities between Grass Valley and Blue Canyon meteorological conditions.

The website, MeteoBlue states: "Climate Grass Valley 39.22°N 121.06°W The meteoblue climate diagrams are based on 30 years of hourly weather model simulations and available for every place on Earth. They give good indications of typical climate patterns and expected conditions (temperature, precipitation, sunshine and wind). The simulated weather data have a spatial resolution of approximately 30 km and may not reproduce all local weather effects, such as thunderstorms, local winds, or tornados."(Meteoblue. 2020. Climate Grass Valley. (Accessed September 2020. https://www.meteoblue.com/en/weather/historyclimate/climatemodelled/grass-valley_united-states-of-america_5353775.)

NOTE: 30 km=18.641 miles The MeteoBlue site is not specific to Grass Valley with a spatial resolution of 30 km. A comparison of downloads in Meteoblue from both locations, Blue Canyon and Grass Valley, shows identical graphic measurements for ALL parameters:

- Average temperatures and precipitation
- Cloudy, sunny and precipitation days
- Maximum temperatures
- Precipitation amounts
- Wind speed
- Wind rose

Because of the 30 km resolution, Meteoblue makes zero distinction between Grass Valley and Blue Canyon weather patterns.

In the Air Quality Report, the consultant utilizes multiple quotes from various county documents, agencies and websites to substantiate his climate and weather claims. For the sake of argument, this critique uses data downloaded from WeatherSpark.com to compare Grass Valley to Blue Canyon meteorology. This website uses the same databases to compare the two locations.

The data for Grass Valley CA is based on a statistical analysis of historical hourly weather reports and model reconstructions from January 1, 1980 to December 31, 2016 (36 years total). The stations contributing to this reconstruction are: Nevada County Air Park (/y/149703/Average-Weather-at-Nevada-County-Air-Park-California-United-States-Year-Round) (67%, 5.0 kilometers, east); Auburn Municipal Airport (/y/145263/Average-Weather-at-Auburn-Municipal-Airport-California-United-States-Year-Round) (24%, 29 kilometers, south); and Beale Air Force Base (/y/145271/Average-Weather-at-Beale-Air-Force-Base-California-United-States-Year-Round) (9%, 33 kilometers, west).

The WeatherSpark data source for Blue Canyon illustrates the typical weather at Blue Canyon-Nyack Airport, based on a statistical analysis of historical hourly weather reports and model reconstructions from January 1, 1980 to December 31, 2016.

3

OTHER DATABASE COMMONALITIES FOR WEATHERSPARK

All data relating to the Sun's position (e.g., sunrise and sunset) are computed using astronomical formulas from the book, Astronomical Algorithms 2nd Edition (https://www.amazon.com/Astronomical-Algorithms-Jean-Meeus/dp/0943396611), by Jean Meeus.

All other weather data, including cloud cover, precipitation, wind speed and direction, and solar flux, come from NASA's MERRA-2 Modern-Era Retrospective Analysis. This reanalysis combines a variety of wide-area measurements in a state of-the-art global meteorological model to reconstruct the hourly history of weather throughout the world on a 50-kilometer grid.

Land Use data comes from the Global Land Cover SHARE database, published by the Food and Agriculture Organization of the United Nations.

Elevation data comes from the Shuttle Radar Topography Mission (SRTM), published by NASA's Jet Propulsion Laboratory.

Names, locations, and time zones of places and some airports come from the GeoNames Geographical Database.

Time zones for airports and weather stations are provided by AskGeo.com.

Maps are © Esri, with data from National Geographic, Esri, DeLorme, NAVTEQ, UNEP-WCMC, USGS, NASA, ESA, METI, NRCAN, GEBCO, NOAA, and iPC

**THE NEVADA COUNTY AIR PARK REFERENCED AS THE WEATHERSPARK SOURCE IS 4000 FEET NE OF THE BRUNSWICK SITE AS THE CROW FLIES.**

GRASS VALLEY

There is an average 10°F higher temperature differential every month of the year in Grass Valley. This conclusion has been verified on WeatherSpark and the Western Regional Climate Center databases. For example, the hot season lasts for 3.1 months in Grass Valley, from June 15 to September 18, with an average daily high temperature above 81° F. In Blue Canyon there is no hot season. The warm season there lasts for 2.9 months, from June 20 to September 18, with an average daily high temperature above 72°F. Average hourly temperatures also vary dramatically between the two locations.

Regarding precipitation: annually Grass Valley receives 53.2 inches rainfall vs 67.5 in Blue Canyon; and annually Grass Valley receives 8.4 inches snowfall vs 240.40 inches snowfall in Blue Canyon.

Wind directions also display wide variances between the two locations. This section discusses the wide-area hourly average wind vector (speed and direction) at 10 meters above the ground. The wind experienced at any given location is highly dependent on local topography and other factors, and instantaneous wind speed and direction vary more widely than hourly averages.

The average hourly wind speed in Grass Valley does not vary significantly over the course of the year, remaining within 0.5 miles per hour of 5.7 miles per hour throughout.

The predominant average hourly wind direction in Grass Valley varies throughout the year. The wind is most often from the south for 7.4 months, from February 10 to September 21, with a peak percentage of 55% on August 11. The wind is most often from the east for 4.6 months, from September 21 to February 10, with a peak percentage

4

of 49% on January 1. (https://weatherspark.com/y/1178/Average-Weather-in-Grass-Valley-California-United-States-Year-Round)

BLUE CANYON

In Blue Canyon, the average hourly wind speed at Blue Canyon-Nyack Airport experiences *mild* seasonal variation over the course of the year.

The *windier* part of the year lasts for *4.3 months*, from *November 19* to *March 30*, with average wind speeds of more than *5.2 miles per hour*. The *windiest* month of the year at Blue Canyon-Nyack Airport is *December*, with an average hourly wind speed of *5.7 miles per hour*.

The *calmer* time of year lasts for *7.7 months*, from *March 30* to *November 19*. The *calmest* month of the year at Blue Canyon-Nyack Airport is *May*, with an average hourly wind speed of *4.8 miles per hour*.

The wind is most often from the **south** for **3.7 months**, from **January 31** to **May 21**; for **3.4 weeks**, from **August 18** to **September 11**; and for **1.1 months**, from **November 3** to **December 7**, with a peak percentage of **48%** on **March 2**. The wind is most often from the **west** for **2.9 months**, from **May 21** to **August 18**, with a peak percentage of **41%** on **July 18**. The wind is most often from the **east** for **1.7 months**, from **September 11** to **November 3** and for **1.8 months**, from **December 7** to **January 31**, with a peak percentage of **41%** on **October 20**. (weatherspark.com/y/145297/Average-Weather-at-Blue-Canyon-Nyack-Airport-California-United-States-Year-Round#)

The Brunswick Industrial site is located just southeast of Grass Valley. This means that the winds will transport all pollutants to the north and west toward the Brunswick Basin and downtown.

It is interesting to note that in Blue Canyon, the wind is blowing east during the hottest part of the year, May 21 to August 18. This input into AERMOD would not correlate with Grass Valley wind data under any circumstances.

These differences in weather variables must be taken into account during HRA modeling since the project will be located in Grass Valley not in Blue Canyon. Using Blue Canyon meteorological data is NOT representative of Grass Valley.

The meteorological input data, AERMET, is designed to accept data from any of the following sources: 1) standard hourly National Weather Service (NWS) data from the most representative site; 2) morning soundings of winds, temperature, and dew point from the nearest upper air station; and 3) on-site wind, temperature, turbulence, pressure and radiation measurements. AERMET can process commercially available or custom on-site meteorological data. (www.weblakes.com/guides/aermod/section8/8_1

SHOULDN'T METEOROLOGICAL DATA MORE REPRESENTATIVE OF GRASS VALLEY BE USED FOR THE HEALTH RISK ASSESSMENT?

**Grp 7-140**

WINDBORNE PARTICULATE MATTER

The following tables are based on Stoke's Law for Fluid Particle Forces and EPA Inhalable Dust definitions and calculations:

5

Table 1: 10-micron particle

| Wind Speed (mph) | Distance Traveled (miles) |
|---|---|
| 3.1 | 0.55 |
| 6.2 | 1.1 |
| 12.4 | 2.3 |
| 24.8 | 4.6 |
| 37.3 | 6.9 |
| 49.7 | 9.2 |

Table 2: 5-micron particle

| Wind Speed (mph) | Distance Traveled (miles) |
|---|---|
| 3.1 | 2.2 |
| 6.2 | 4.5 |
| 12.4 | 9 |
| 24.8 | 18 |
| 37.3 | 27 |
| 49.7 | 36.1 |

(http://toxsci.oxfordjournals.org/content/65/1/7.full (including impacts/effects of airborne sulfur (SO2) and silica particulates/particles)

The average wind speed in Grass Valley is 5.7 mph. The Brunswick Site is located 2 miles from downtown Grass Valley. As evidenced above, the smaller the particle, the greater the distance travelled. Grass Valley currently monitors PM 2.5 at the Litton Building. Nevada County is currently classified as nonattainment status for PM10.

The International Agency for Research on Cancer of the World Health Organization has classified PM2.5 as a human carcinogen (*IARC: Outdoor Air Pollution a Leading Environmental Cause of Cancer Deaths; Technical Report; International Agency for Research on Cancer (IARC): Lyon, French,27 2013)*

On September 22, 2021 the World Health Organization revised air quality guidelines decreasing criteria air pollutants, especially the recommended exposure levels for PM10 and PM2.5. (https://www.iqair.com/us/blog/air-quality/2021-WHO-air-quality-guidelines

Has a baseline scenario for Grass Valley PM2.5 emissions or PM10 emissions been created since Nevada County is in nonattainment status for PM10? Were background PM2.5 concentrations from long range sources added to the HRA model?

A baseline concentration must be established in order to measure the TRUE impact from the addition of this project to existing air quality and the cumulative impacts on community health.

**Grp 7-141**

DPM, silica and asbestos fugitive dust will be emitted under two different categories: criteria air pollutants and as Toxic Air Contaminants. Yet in each situation, their health impacts to the community will be minimized.

As a criteria air pollutant, emission levels are not related to the immediate geographical area: "Notably, as detailed in Appendix C, there are numerous scientific and technological complexities associated with correlating criteria air pollutant emissions from an individual project to specific health effects or potential additional nonattainment days, such as the disconnect between mass emissions and concentrations due to secondary pollutant (such as O3) generation and pollutant transport, as well as the inaccuracy of applying regional and population-wide models to a local level in order to estimate health effects, and there are currently no modeling tools endorsed by an expert agency (i.e. NSAMQD) that could provide reliable and meaningful additional information regarding health effects from criteria air pollutant generated by individual projects." ***(Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project, pg 46, 2021)***

As a toxic air contaminant, asbestos and respirable crystalline silica will fall under the non-criteria air pollutant category. There are no established limits for monitoring emissions of non-criteria pollutants into the ambient

6

environment. The HRA is based on 30 years of exposure, thus the cumulative effects of the 80-year permit are not addressed.

**Grp 7-142**

**Grp 7-143**

HOW WILL THE RELEASE OF THESE TOXIC MICROSCOPIC PARTICULATES TO THE AMBIENT ENVIROMENT BE MONITORED?

SENSITIVE RECEPTORS

**Grp 7-144**

When listing *Receptors Used for Evaluating Modeled Impacts* are the following statements: "There are existing residences in all directions of the project site, with the nearest located north of East Bennett Road at approximately 100 feet from the project boundary. The nearest hospitals and schools to the project sites are the Sierra Nevada Memorial Hospital on Glasson Way (approximately 1800 feet north of the Centennial Industrial Site) and the Montessori House of Children on The Burma Road (approximately 2,500 feet south of the Brunswick Industrial Site boundary). However, residential receptors are the most conservative to evaluate as discussed further in Section 4.3." (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 7, 2021*)

What about the impacts to the following receptors?

The Durham School Bus Depot is located 1.74 Miles west of the Brunswick Industrial Site on Bennett Road. These buses transport our children throughout the county. Will we be delivering asbestos and silica dust along with the children?

Within a 2-mile arc north of the Brunswick Industrial Site are 5 Skilled Nursing Facilities (Golden Empire, Wolf Creek, Atria Memory Care, Spring Hill Manor, and Crystal Ridge), at least 6 Assisted Living Facilities, 10 low-income housing apartment complexes, Hospitality House and Brunswick Commons housing for the homeless. All supportive services are located here as well: Pride Industries, FREED, Alta Regional Center, DaVita Dialysis, Nevada County Public Health offices and Connecting Point. Chapa-De Indian Health and multiple physicians' offices serving Medi-Cal patients are located here too.

**Grp 7-145**

According to the 2020 US census, 28.6% of Nevada County is 65 years or older as compared to the statewide rate of 14.3% for that population. Under age 65, the disability rate is 14.4% and 32.4% of the population have Medicaid coverage. The mortality rate from Chronic Lung Disease is double the state wide rates (69.26 deaths/100,000 people vs 34.92/100,000). There are also elevated rates for Heart Disease Mortality, Hypertension Mortality, Stroke Mortality and All-Cause Cancer Mortality vs state wide rates.

The demographics of our community must be considered in the context of this project. We already have elevated baselines for high levels of the criteria air pollutants ozone and particulate matter, radon, aging population, chronic disease, and poverty.

WILL THE COUNTY'S EXISTING BASELINES BE TAKEN INTO ACCOUNT?

SOURCE RELEASE SCENARIO

**Grp 7-146**

Table 2. Emission Source Parameters

DIESEL FUEL

These parameters are used to input data into the AERMOD dispersion model. On Page 10 of the HRA, the generators are listed at a Base Elevation of 2,748.39 m. This calculates to a height of 9017 feet. The Brunswick

7

Diesel Storage Tank is listed at a Base Elevation of 2,757.74 m which equals a height of 9048 feet and the Centennial Diesel Storage Tank is listed with a Base Elevation of 2,491.44 m which equals 8174 feet. These measurements are used to estimate carcinogenic volatile organic compound emissions from breathing and working losses from storage tanks which include benzene, hexane, toluene and 2,2,4-trimethylpentane. *Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, Pg 23, 2021)*

All data entry inputs should be verified in AERMOD model due to these errors, especially units of measure, which may be affected for other source parameters (i.e. plume height/plume width of 25/25 meters for line sources).

Diesel fuel combustion from generator use will exhaust gases and DPM. These estimated emissions have been included for only 100 hours per year during testing/maintenance. Any emissions from actual use have been categorized as speculative. During a Public Safety Power Shutoff (PSPS), it is anticipated that 15,000 gallons of diesel fuel combustion per day will be required to maintain mining operations.

**Grp 7-147**

Will diesel fuel consumption be monitored? Will there be any provisions to mitigate the impacts from PSPS generator use contributing to increased criteria air pollutants, GHGs and DPM emissions affecting the community and environment?

Will there be any penalties if Tier 4 Final engines are not used exclusively due to "commercially available" status exemptions?

FUGITIVE DUST

SILICA

Silica will be released from on-road vehicles, underground blasting and crushing, ore processing along with earthwork and material handling.

All of the consultants have stated in their reports that they are using information provided by Rise to generate their conclusions. A prime example is the silica emissions. The following table shows the anticipated rock types and amounts expected to be mined:

**Grp 7-148**

| Rock Type | Percent of Total |
|---|---|
| Meta-Andesite | 96% |
| Altered Meta-Andesite | 2% |
| Diabase | 1% |
| Serpentinite | 1% |

This chart represents the anticipated barren rock ratios to be mined, approximately 500 tons per day. It does not account for the 1000 tons of mineralized ore rock to be mined each day. (*Groundwater Hydrology and Water Quality Analysis, EMKO, pg 93)*

"The applicant estimates that the ore processed would be quartz veins hosted primarily within andesite rock and an assumed 60% silica content."( *Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 35, 2021)*

8

Regarding rock composition, this is meta-andesite rock not just andesite…it has undergone metamorphosis becoming altered in composition. Johnston (1940) stated: "The degree of metamorphism may vary in this unit, such that parts of it have been referred to as amphibolite schist, porphyrite, diabase, and quartz porphyrite." (*The Gold Quartz Veins of Grass Valley, referenced in Groundwater Hydrology and Water Quality Analysis EMKO pg 9)*

The laboratory that Rise used for all metals analyses, ACZ Laboratories, is certified to perform both silica and silicon dioxide tests yet not a single sample was analyzed for this parameter. *(ACZ Analytical Capabilities 2017).*

The engineering firm, NV5, stated in the *Centennial Geotechnical Report* (pg 12) that: "We understand that the sand tailings will likely have a gradation similar to the historical gradation presented in the table below, and will typically have a large proportion of quartz."

| Mesh Size | Particle Size (mm) | Particle Size (micron) | Percent Passing | Description |
|---|---|---|---|---|
| 48 | 0.300 | 300 | 97.7 | Medium Sand |
| 65 | 0.212 | 212 | 87.5 | Fine Sand |
| 100 | 0.150 | 150 | 63.9 | Fine Sand |
| 200 | 0.075 | 75 | 32.3 | Silt |
| 325 | 0.044 | 44 | 12.1 | Silt |

Quartz is 100% silicon dioxide AND "1000 tons of ore" rock will be processed into tailings each and every day, *Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix, B pg 21, 2021).*

These tailings will contain respirable crystalline silica, a toxic air contaminant. Rise has assumed that the ore rock is 98% andesite with a silica content of 60%. There is no data to substantiate this assumption. Minimizing the levels of this TAC to be generated from the excavation of material and milling of quartz greatly diminishes its' impact in the HRA considering the vast amounts, 1500 tons of barren and ore rock, to be mined each day.

HOW WILL THE COMMUNITY PROTECT ITSELF FROM UNKNOWN QUANTITIES OF SILICA?

ASBESTOS

Asbestos will be released from on-road vehicles, during underground blasting and crushing, ore processing and along with earthwork and material handling.

**Grp 7-149**

The rock composition chart above lists total serpentinite mined at 1% yet the *Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Earthwork and Material Handling Fugitive Dust: Construction Activity Fugitive Dust* assumes *Serpentinite Content of Mine Fill* at 14.3%. Based on the given information, daily mine fill content is composed of 500 tons of tailings and 500 tons of barren rock at 1% serpentinite.

With these ratios, how can engineered fill contain 14.3% serpentinite?

**Grp 7-150**

Rise has developed an Asbestos, Serpentinite and Ultramafic Rock management plan with the goal of minimizing asbestos release. A 90-day rolling inventory will be maintained in an effort to prevent asbestos contaminated material from being used as aggregate and engineered fill. A three-grab composite sample will be obtained for every 1000 tons mined. The sampling point is located mid drop in the silo. Inventory material will then be screened using Polarized Light Microscopy (PLM), followed by Transmission Electron Microscopy (TEM) testing with results to be mathematically converted to Phase Contrast Microscopy (PCM) equivalent units. These tests are not comparable since they utilize different preparatory methods, sample amounts and microscopy techniques. The detection limit for PLM testing is 0.25% and the detection limit for TEM testing is 0.001%. Conversion of TEM to PCM equivalent units yields a detection limit of 0.01%.

9

Under this plan, Rise is using the PCM equivalent units limit of 0.01% to calculate emissions levels for fugitive dust. "A conservative approach for the modelling of TAC emissions is used, with the asbestos content in mined materials assumed at the maximum of 0.01% by mass of PCM equivalent units. The average asbestos content of the mined material is of primary concern since asbestos does not have established acute noncancer effects (OEHHA)"(*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, pg 22, 2021*).

Initial asbestos sampling of 42 samples (*Asbestos Sampling Memo June 2020*) resulted in two samples at 0.075% and 2.5% by PLM analysis along with two samples at 2.0% and 3.1% by TEM analysis. The remaining 38 samples were non-detect (<0.25%) by PLM. Re-testing of these PLM samples by TEM yielded 6 samples with results greater than the PCM equivalent units detection limit of 0.01% in addition to the original 2 TEM samples that were not re-tested. Thus, **twenty percent** of the samples had asbestos levels greater than 0.01% PCM equivalent units.

Excluding the two grab tailings samples from Centennial and the two blanks, the average overall length of a sample core tested for asbestos was 5.34 inches. Samples were from 6 of 19 (32%) of total cores drilled by Rise: 9 samples from I-18-11, 1 sample from I-18-12, 9 samples from I-19-13, 7 samples from I-19-13A, 8 samples from I-19-14 and 4 samples from I-19-14A. Drilling was stopped when asbestos was detected. Drill logs are not available, no information available as to quantity, location, depth, etc. These cores appear to be in close proximity to each other as viewed on geological maps (*Asbestos Sampling Memo June 2020 pp 11-13*).

DEIR pg 3-20: "The ASUR plan incorporates routine asbestos testing by Transmission Electron Microscopy (TEM) and an Asbestos Inventory to ensure that average mined material and engineered fill contains less than 0.01% asbestos by mass of Phase Contrast Microscopy (PCM) equivalent units."

Just because Rise believes that they will be able to control the distribution of material to 0.01% asbestos content does NOT mean that they can control the amount of asbestos in the actual mined material. The content of asbestos in the serpentinite is unknown until tested-this requires blasting, excavation, crushing, skipping, conveyance to the surface, deposition and storage to then be followed by testing. Ventilation from the mine during these underground processes will emit asbestos to the ambient environment. This quantity of asbestos emissions is unknown and CANNOT be assumed to be only 0.01%.

**Grp 7-151**

The ASUR Plan dictates the use of water curtains and an auxiliary fan system when mining serpentinite material. According to Rise, this system uses MERV 16 filters that will trap particles to 0.03 microns reducing asbestos fibers by 95% before the fibers enter the main ventilation system. How much asbestos will be in the remaining 5% if the initial asbestos content of the rock is unknown along with the unknown quantities of rock mined?

Maintenance of the 0.01% inventory will not be attemptable until AFTER the material is mined, brought to the surface and tested twice- requiring up to two weeks before the results are known.

These asbestos emissions are not accounted for in fugitive dust estimations.

**Grp 7-152**

In 1986, asbestos was identified by the Board (CARB) as a toxic air contaminant: the Board also determined that there is not enough scientific evidence to identify an asbestos threshold level below which no significant adverse health effects are anticipated (17 CCR 93000). (*Implementation Guidance Document 2017, CARB pg 1*)

The World Health Organization (WHO) concurs that there is no safe level of asbestos exposure. Any asbestos released to the ambient environment will create chronic exposure risk for the community since asbestos does not readily degrade. Protecting mine workers from acute exposure when mining material "rich in asbestos" does not equate to the same level of community protection. Under these circumstances, miners will work a short-shift, wear respirators, be monitored for exposure, and decontaminate themselves before going home. They have the freedom of choice to work in that environment, financial compensation, training in exposure control and health care benefits. The community has none of these protections.

By using the detection level of 0.01% mass by PCM equivalent units to calculate emissions used in the HRA, the levels of this TAC have been grossly underestimated.

10

HOW WILL THE COMMUNITY PROTECT ITSELF FROM UNKNOWN QUANTITIES OF ASBESTOS?

HEAVY METALS

"Blasting and crushing would also result in emissions of dust with trace heavy metals TACs including arsenic, beryllium, cadmium, copper, lead, manganese, mercury, nickel, selenium, and vanadium. Concentrations of each heavy metal within the barren rock and mineralized rock was taken from Table 4-7 of the *Groundwater Hydrology and Water Quality Analysis Report for the Idaho-Maryland Mine Project* (EMKO Environmental, Inc. 2020)"

Heavy metals will be released: from off-road equipment, on-road vehicles, during underground blasting and crushing, ore processing along with earthwork and material handling-all phases of operations.

The data used for heavy metal toxic air contaminants in the Health Risk Assessment are all notated by the laboratory as being received and tested beyond the EPA recommended hold times of 28 days for mercury and 6 months for all remaining metals. Exploratory drilling began in 2017. Since the drill logs are unavailable, the exact sample dates for each core are unknown, but all samples were submitted and received by the gold assay laboratory on February 20, 2019. (*Appendices: Groundwater Hydrology and Water Quality Analysis EMKO, pp 515-516*) and (Appendices: *Groundwater, Hydrology and Water Quality Analysis Report: Inorganic Extended Qualifier Reports pp. 389-407 and 458-484)*

**Grp 7-153**

After assays were performed, samples were then submitted to ACZ Laboratories for metal analyses. It is not clear where the samples were located between the assay lab, ALS Laboratories in Reno, Nevada and submission to ACZ Laboratories in Steamboat Springs, Colorado. The Chain of Custodies describe these 47 samples as Tailings (assay pulp). All list a sample date of 3/5/19:12:00 pm. Under the Sampler's Name were the initials, BM (Ben Mosssman?) Ben Mossman and Andrew Kopania of EMKO both received copies of the laboratory reports as listed on the CoCs. The laboratory received by date for all samples is 11.11.2019. Twenty samples were digested on 11.22.2019 and the remaining twenty-seven samples were digested on 11.26.2019. (The digestion dates would be used for endpoint hold time calculations).

These samples may have been collected at that time but they were NOT sampled at that time. These metals analyses were performed in November 2019 in two batches. This means that all samples were tested at least 9 months beyond their hold time expiration date, probably more.

Potentially toxic elements (PTEs) hosted in asbestos elongate mineral particles is one of the factors that determines their toxic/pathogenic effects. Metals such as Fe, Mn, Cr, and Be are known to induce toxicity and contribute to asbestos related diseases. "...it is essential to quantify the toxic elements present in asbestos elongate mineral particles in order to prevent asbestos-related diseases." (https://doi.org/10.1016/j.chemgeo.2020.119896Get rights and content)

SHOULDN'T VALID DATA BE USED WHEN EVAUATING THE HEALTH RISKS TO THE COMMUNITY FROM THESE TOXIC AIR CONTAMINANTS, ESPECAILLY WHEN THESE METALS HAVE THE ABILITY TO POTENTIATE THE EFFECTS OF ASBESTOS?

CONCLUSION

**Grp 7-154**

"Based on the PM10 emissions estimated, emissions of asbestos, silica, and heavy metals were estimated for the purposes of this HRA." (*Air Quality and Greenhouse Gas Emissions Analysis Report for the Idaho-Maryland Mine Project: Health Risk Assessment, Appendix B, Pg 22)*

11

Estimations of estimates...estimates of estimations

IS THERE ANY VALIDITY IN ANY OF THESE ASSUMPTIONS, ESTIMATIONS OR DATA REGARDING THE EMISSIONS OF SILICA, ASBESTOS, HEAVY METALS OR DPM?

IS THERE ANY VALIDITY TO THIS HEALTH RISK ASSESSMENT OF OUR COMMUNITY?

Please include these comments to the Idaho-Maryland Mine DEIR.

SAMPLING PROCEDURES

**Grp 7-155**

Page 93 of the *Groundwater Hydrology and Water Quality Analysis Report*, EMKO states that Rise completed 19 drill core holes, totaling 67,500 linear feet, from 2017-2019. The sampling pattern was to drill 90 feet, pull a 10-foot sample segment, drill another 90 feet, etc. The drill logs are not available for review; the actual dates, precise locations, drift angles, widths, final depths, etc. are unknown.

"The cores were sawed in half in zones of interest and sent to ALS in Reno, Nevada to be assayed. ALS Laboratories crushed and homogenized the sample to ~2 mm size, split a 1 kg sample, pulverized the split sample, and assayed a split of the pulverized sample." (*Groundwater Hydrology and Water Quality Analysis Report* pg 93) Samples were received on 02.20.2019 with a finalized date of 03.05.2019. (*Appendices: Groundwater Hydrology and Water Quality Analysis Report pp 515-516*)

After assay for gold, the samples were subjected to additional testing at different laboratories.

**Grp 7-156**

METALS ANALYSES, DI-WET, ABA, WET CHEMISTRY PARAMETERS

FLOTATION COMPOSITE- McClelland Labs

"A composite sample was prepared from 76 samples of the ~2 mm material remaining from assaying. A portion of the material was weighted to represent the interval length and merged to make the metallurgical sample. Sufficient material was available for most samples, except for five samples where no material was available from the assay lab. The 76 samples created a composite metallurgical sample of approximately 46 kilograms (kg) (100 pounds)". (*Groundwater Hydrology and Water Quality Analysis Report pp 95-96*). This composite was sent to McClelland Labs in July 2019 which then homogenized the sample and split it into 4 sub-samples, F1-F4 flotation tailings samples. Page 537 of *Appendices: Groundwater Hydrology and Water Quality Analysis Report* states: "A total of 7 buckets containing 6 separate samples were received from the Maryland mine on July 10, 2019. The

1

samples weighed 4 to 47 kg, and appeared to be approximately -6 mm in size. The largest sample ("flotation composite") was intended for analysis..."

Is the material 2 mm or 6 mm in size? What is the exact provenance of the 76 samples that comprise the composite as it relates to the 47 cores submitted for assay?

After flotation testing, these samples were shipped from McClelland Labs to a geologist at Benchmark Resources in Folsom, CA during November 2019 who then submitted the samples to ACZ Laboratories in Steamboat CO. These samples, F1-F4, were then analyzed by ACZ for total metals, DI-Wet metals, Static Acid-Based Accounting and wet chemistry parameters.

BARREN ROCK-ACZ Laboratories

**Grp 7-157**

On October 29, 2019 a geologist with Benchmark Resources selected barren rock samples: MA-1, MS-1, MA-2, MAA-1, S-1 and MA-3 from Rise Grass Valley. These samples were from 3 different cores [1 sample from I-18-10, 1 sample from I-18-11 and 4 samples from I-19-13 (*Groundwater Hydrology and Water Quality Analysis Report, EMKO pg 93)*], with combined segments equaling 34.1 linear feet. This represents only 0.05% of 67,500 total linear feet.

They were submitted to ACZ Laboratories in November 2019 to be tested for total metals, DI-WET metals, Static ABA and wet chemistry parameters.

METALS ANALYSES-BARREN ROCK CRUSHED CORES-ACZ Laboratories

Samples submitted for metals testing with identifiers can be found in Table 4-9 Barren Rock Crushed Core Samples: Total Metals Results in *Groundwater Hydrology and Water Quality Analysis Report, EMKO pp 101-102*.

**Grp 7-158**

Regarding the barren rock crushed core metals analyses, only 5 cores were tested which means that only 26% of the 19 total cores were sampled [1 sample from B-18-02, 3 samples from I-18-10, 1 sample from I-18-11, 2 samples from I-18-12 and 40 samples from I-19-13 (*Groundwater Hydrology and Water Quality Analysis Report, EMKO pp 101-102*)]. All five core segments combined length equal a total of 456.5 linear ft. These combined 10 ft segments represent only 0.68% submitted for testing compared to total of 67,500 ft. In general, each sample represents 10 linear feet. The diameter of the cores is not given. It is not stated how much material, weight wise or volume, is contained in each segment or specifically how that material is "homogenized" to obtain a representative sample for testing.

After assay at ALS Laboratories, the samples were labelled as "Pulp-2, Tailings= (assay pulp)". These 47 samples were then analyzed by ACZ Laboratories for total metals. The final weight used in metals analysis is 1-2 grams of material per sample.

**Grp 7-159**

The reference for this "Crush and Pulverize" step is EPA 600/2-78-054 3.1.3 (Field and Laboratory Methods Applicable to Overburdens and Minesoils, March 1978 pp. 43-45). The Foreword states "This report provides chemical, physical, mineralogical, and microbiological procedures for the analysis of coal overburdens and the resultant minesoils. These step-by-step methods identify and measure rock and soil properties that influence advance planning, mining efficiency, post-mining land and water quality and long-range land use."

2

Procedure (3.1.3):

1. Pour field sample onto a large square of brown paper. Spread material evenly and allow to air dry. NOTE: Sample may have to be mixed periodically to speed drying.
2. After drying, the field sample is split into two representative subsamples. One subsample is placed in a container, labeled, and stored for physical analyses or individual preference tests.
3. The other subsample is placed between two sheets of brown paper and crushed by moderately rolling over the top sheet with a rolling pin. This process is continued until the entire field sample has been processed. NOTE: Do not allow paper fragments to become incorporated with the soil sample. Do not crush rock fragments.
4. Pass the crushed material through a sieve with 19 mm openings and discard material retained on the sieve.
5. All material passing the 19 mm sieve is crushed to pass through a sieve with 6.35 mm openings.
6. Place sieved sample in a 1 liter container and cover. NOTE: Container should not be more than two-thirds full or mixing (step 7) will be impaired.
7. Tumble container end-over-end until material is thoroughly mixed.
8. Place three heaping teaspoons of the mixed material in the pulverizer. Material is pulverized until it passes a 0.25 mm (60 mesh) sieve. NOTE: A cast iron mortar and pestle can be substituted for the pulverizer.
9. Place pulverized material in a plastic vial for laboratory use.
10. Label vial with the sample identification shown on the field container.
11. Mix sample thoroughly by tumbling the vial end-over-end before subsampling for laboratory procedures (primarily chemical analyses).

After a sample is obtained, according to test method, M3050B (SW-846) Acid Digestion of Sediments, Sludges and Soils, a 1 gram (dry weight) of sample is digested for ICP-MS metals analyses testing. The digestate is then diluted to a final 100 ml volume. Flow injection volumes generally range from 20µl-200µl (microlilter) from the 100 ml prepared volume. A µl (microliter) is equal to 0.001 milliliter(ml) or 1/1000$^{th}$ of ml. Analyses dilution factors range from 1 to 500. For reference: There are 1 million grams in a metric tonne.

All metals were digested using EPA Method 3050B. The results should be defined as the "Total acid soluble/recoverable metals" fraction since this method does not use hydrofluoric acid, thus it is unable to break down silicates. (EPA SW-846 Revision VI December 2018, Chapter 3, pg 4)

ACZ Laboratories did receive "pulp" samples, residual material after ALS gold assay analyses. "In addition to the barren rock samples, Rise provided 48 crushed core samples, taken from ~2 mm assay rejects, for trace element test work." (*Groundwater Hydrology and Water Quality Analysis Report, EMKO, pg 95*) The actual number of samples was 47.

The barren rock samples must be pulverized prior to acid digestion just as the 47 "pulp" samples were pulverized prior to analysis for metal analyses. Any conclusions comparing metals content, leachate capacity, ABA, etc. between pulp results and barren rock results is moot since the sample preparation (pulverization) is identical.

**Grp 7-160**

TESTING TIMELINES

3

After exploratory drilling, cores were sent to ALS Laboratories which were received on 02.20.2019. Date finalized 03.05.2019. "The cores were sawed in half in zones of interest and sent to ALS in Reno, Nevada to be assayed. ALS Laboratories crushed and homogenized the sample to ~2 mm size, split a 1 kg sample, pulverized the split sample, and assayed a split of the pulverized sample." (*Groundwater Hydrology and Water Quality Analysis Report* pg 93)

Then the composite sample was prepared and sent to McClelland Labs for flotation testing from July 2019- November 2019. Samples F1-F4 were then sent to ACZ Laboratories for metals testing, DI Wet testing, ABA and wet chemistry parameters. The Flotation Results Report from McClelland Labs was not submitted to Rise until January 29, 2020.

Also in November, 2019, the 47 crushed core samples were sent to ACZ for metals testing along with the six barren rock samples to be tested for metals, DI WET metals, ABA and wet chemistry parameters.

It is difficult to understand how the composite sample was prepared and analyzed months before the individual samples (barren rock and barren rock crushed core) were submitted to ACZ in November 2019. The chains of custodies do not reflect the written account. Other than the out-going COC from McClelland to Benchmark Resources regarding F1-F4 samples, all sample shipments originate from Rise Grass Valley. The transitions between the various laboratories are not documented regarding dates, amounts, sample containers, etc.

SAMPLE POPULATIONS

FLOTATION COMPOSITE

"A total of seven buckets containing six separate samples were received from the Maryland Mine on July 10th, 2019. The samples weighed 4 to 47 kg, and appeared to be approximately 6 mm in size. The largest (flotation composite") was intended for analysis and metallurgical testing as well as environmental characterization of the testing products... The five remaining samples were indicated to be waste rock samples of various types for environmental characterization. Preparation and analysis of the waste rock samples will be discussed in a separate report." (*Appendices*: *Groundwater Hydrology and Water Quality Analysis Report: Appendix H, pg 2)*

**Grp 7-161**

"The rougher tailings from two selected tests were also subjected to environmental characterization (discussed in a separate report)." (*Appendices*: *Groundwater Hydrology and Water Quality Analysis Report: Appendix H, pg 4)*

The flotation composite arriving in a bucket is not a very specific provenance considering that these tailings will be used to determine heavy metal leachates. What material was in this bucket?

What is environmental characterization of the testing products? What is the environmental characterization of the waste rocks? Where is the separate report that describes the preparation and analysis of the waste rock and rougher tailings for "environmental characterization"? Is the environmental characterization part of the Cement Paste Backfill study?

4

BARREN ROCK SAMPLES

The three cores represent a 15.8% sample population when compared to 19 total cores. Samples MA-1(I-19-13), MS-1(I-19-13), MA-2 (I-19-13), MAA-1(I-19-13), S-1(I-18-11) and MA-3 (I-18-10) were each tested for barren rock total metals, barren rock leachate DI-WET, barren rock Static Acid-Based Accounting, and Wet Chemistry parameters. In addition, samples MA-1, MS-1 and MA-1 were assayed for gold determination.

BARREN ROCK CRUSHED CORE SAMPLES

**Grp 7-162** Metals analyses for forty out of forty-seven representing 85% of the total rock core samples were from a single drill core, I-19-13, at various depths (167 ft bgs to 4774.6 ft bgs = 4607.6 total feet). These samples represent 6.8% sample population when compared to 67500 total linear feet. In addition, 25% of this core is missing between depths 3227.0-3583.0 = 356 ft, 3969.7-4313 = 343.3 ft and 4323.0-4767.9 = 444.9 ft. These missing sections total 1144.2 ft out of 4607.6 feet. The remaining 3463.4 feet represent a 5.1% sample population compared to the 67500 total linear feet.

CONCLUSION

**Grp 7-163** It is obvious that very limited sampling and testing has been done. Only one sample, B-18-02, was analyzed from the "Brunswick" area- metals analyses were performed on the barren rock crushed core sample. Rise plans to mine in this area immediately along with the installation of major infrastructure.

**Grp 7-164** There are egregious issues with the Chains of Custody regarding sample dates, locations and quantities. Samples from only 5 cores are represented out of 19 total cores. Eight five percent of total metals analyses (barren rock crushed cores) were performed on one core, I-19-13, while 67 % of barren rock total metals, leachate Di-WET testing, wet chemistry along with ABA testing were performed on this same core.

**Grp 7-165** There are inconsistencies and omissions within this limited sampling as well. For example, S-1 is taken from core I-18-11 at a depth of 4725.6'-4725.7'. This is a total of 0.1 feet or 1.2 inches. The diabase sample above it (Y973586) is taken at 4107.8-4117.55'. What is between these two samples with 608.05 feet missing? Where did the serpentinite layer begin? How deep is the serpentinite layer beneath since sampling stopped after 1.2 inches?

**Grp 7-166** Sample (Y973596) from core I-19-13 at 4767.9'-4772.7' is listed as MA in the Hydrology report but as Meta volcanic serpentinite on ALS COC. Sample (Y973597) from core I-19-13 taken from 4772.7'-4774.6' is serpentinite also. What is below this level where sampling stopped after 1.9 feet? This is known serpentinite containing asbestos.

QUALITY CONTROL ISSUES

**Grp 7-167** Regarding static acid-base-accounting, page 510 of the *Appendices: Groundwater Hydrology and Water Quality* states that the following parameters are not offered for certification or are not covered by NELAC certificate #ACZ:

| | |
|---|---|
| Neutralization Potential as CaCO3 | M600/2-78-054 NV Modified Sobek Procedure |
| pH, Saturated Paste | EPA 600/2-78-054 section 3.2.2 |
| Sulfur HCl Extractable | M600/2-78-054 3.2.4 & 3.2.6 Modified Sobek Procedure |

5

| | |
|---|---|
| Sulfur HNO3 Extractable Procedure | M600/2-78-054 3.2.4 & 3.2.6 Modified Sobek |
| Sulfur Hot H2o Extractable Procedure | M600/2-78-054 3.2.4 & 3.2.6 Modified Sobek |
| Sulfur Residual Procedure | M600/2-78-054 3.2.4 & 3.2.6 Modified Sobek |
| Sulfur Total Procedure | M600/2-78-054 3.2.4 & 3.2.6 Modified Sobek |

Lack of certification impacts validity of acid-base-accounting results for all samples: MA-1, MA-2, MA-3, MAA-1, MS-1, S-1, F-1, F-2, F-3 and F-4 (pp 495-504, Appendices: *Groundwater Hydrology and Water Quality Analysis Report*).

SILICA

Toxic air contaminants, silica and asbestos, will be produced daily in massive quantities. Silica content is assumed as 60% quoting a textbook definition of andesite rock composition. But 98% of the total rock mined is assumed to be meta-andesite. Regarding rock composition, meta-andesite rock is not just andesite....it has undergone metamorphosis becoming altered in composition. Johnston (1940) stated: "The degree of metamorphism may vary in this unit, such that parts of it have been referred to as amphibolite schist, porphyrite, diabase, and quartz porphyrite." (*The Gold Quartz Veins of Grass Valley, referenced in Groundwater Hydrology and Water Quality Analysis EMKO pg 9)*

**Grp 7-168**

500 tons of barren rock will be mined each day.

Mineralized ore rock, gold in quartz (100% silicon dioxide) veins, has not been accounted for in silica calculations.

1000 tons of ore rock will be mined each day.

Silica content was not tested on any samples even though the methods utilized, ICP-MS, can analyze for both Silicon (Si) and Silica ($SiO_2$) and more specifically can be performed by their contracted laboratory-ACZ Laboratories (*ACZ Analytical Capabilities 2017*).

What is the actual silica content of the barren rock and ore rock?

ASBESTOS

**Grp 7-169**

Forty-two samples were analyzed for asbestos: two blanks, 2 Centennial tailings and 38 drill core samples. The core samples were from 6 of 19 (32%) of total cores drilled by Rise: 9 samples from I-18-11, 1 sample from I-18-12, 9 samples from I-19-13, 7 samples from I-19-13A, 8 samples from I-19-14 and 4 samples from I-19-14A. The average overall length of the sample cores tested was 5.34 inches. Drilling was stopped when asbestos was detected. Drill logs are not available, therefore unable to determine depth or width of serpentinite deposit encountered. Asbestos sampling was limited. Centennial tailings were only identified by grid number-no information as to quantity, location, depth, etc.

Rise states that 1% of material mined each day will be serpentinite (*Groundwater Hydrology and Water Quality Analysis Report*, pg 93). Yet all of the geological maps located in the *Technical Report for the Idaho-Maryland Mine Project* show the quartz veins running with the

6

contact points of the faults along the serpentinite deposit (AMEC 2017 pp 7-17, 7-23, 9-9, 9-11, 9-26).

The *Air Quality and Greenhouse Gas Emissions Analysis Technical Report: Earthwork and Material Handling Fugitive Dust: Construction Activity Fugitive Dust* Nov 2021 pg 300 states that the serpentinite concentration of Mine Fill will be 14.3%. How can the mine fill concentration be seven parts serpentinite when it comprises only 1 % of material mined?

"Exploration drilling was designed to test a variety of mineralization throughout the deposit in areas where mining is expected to occur." (pg 93, Hydrology Report) "Rise selected mineralized samples for metallurgical testwork by reviewing drill logs and maps. Samples were selected to represented (sic) materials representative of future mining. Factors considered in selection were gold grades, minimum mining widths, mineralization style, and locations throughout the potential mining areas." (pg. 95 Hydrology Report)

CONCLUSIONS

**Grp 7-170** How can the actual ratios of rock mined be known based on this work? This information is necessary to determine emissions of toxic air contaminants such as heavy metals, silica and asbestos.

**Grp 7-171** Why wasn't more testing done on the Brunswick area since mining is anticipated to begin there immediately along with the installation of major infrastructure?

**Grp 7-172** How can the data from this limited sampling be extrapolated to 2585 acres being mined to unknown depths for the next 80 years?

Thank you,

**Re: Comments on the Draft EIR for the Idaho-Maryland Mine Project**

From: David M. Chambers, Ph.D., P. Geop.

**Background**

David Chambers has 40 years of experience in mineral exploration and development – 15 years of technical and management experience in the mineral exploration industry, and for the past 30+ years he has served as an advisor on the environmental effects of mining projects both nationally and internationally. He has Professional Engineering Degree in physics from the Colorado School of Mines, a Master of Science Degree in geophysics from the University of California at Berkeley, and is a registered professional geophysicist in California (# GP 972). Dr. Chambers received his Ph.D. in environmental planning from Berkeley. His recent research focuses on tailings dam failures, and the intersection of science and technology with public policy and natural resource management.

Grp 7-173

**OVERALL COMMENT**

This is a rather unusual mine project proposal, a request for an 80-year operating permit, in that most regulatory agencies would consider the level of information presented for this environmental review of the project sufficient only to consider this as a proposal for advanced exploration, not for mine development. This mine development proposal lacks the economic and environmental data necessary to evaluate a full mine development proposal.

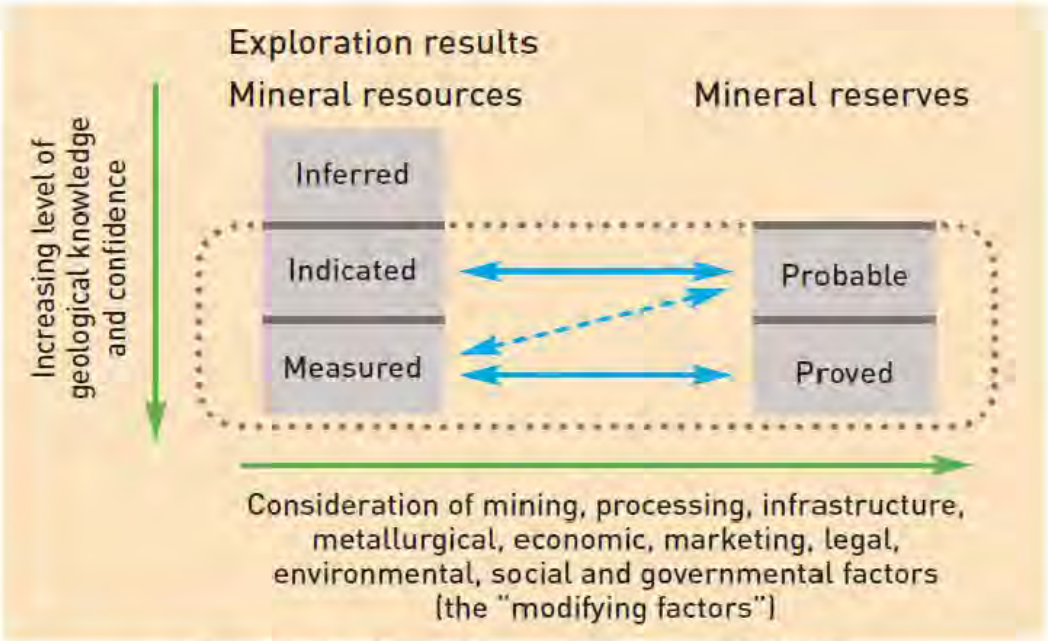
Grp 7-174

Unlike a typical mine that is being proposed for production, the Idaho-Maryland mine; (1) does not have an identified mineral reserve, or even a mineral resource; (2) the drilling core is not sufficient to provide the necessary information on the geochemistry of the waste rock and tailings; and, (3) there is no surface water-quality modeling. These are all elements that are critical in evaluating the potential impacts of a proposed mine.

As a result, it is not known whether the mine waste could leach contaminants into ground and/or surface waters. The design details of the "engineered fill" facility have yet to be done, so it not known if the proposed design is geotechnically sound. In addition, the long-term closure costs for the mine have not been analyzed.

Page #2

**SECTION-SPECIFIC COMMENTS**



**3.6 Project Objectives**

In order to have a credible mine proposal, a minimum amount of ore must be identified to warrant the economic investment to open a mine. It is possible that a mining company has enough capital to self-fund the hundreds of millions of dollars necessary to bring a mine property like Idaho-Maryland to the point where it is ready to produce its first ounce of gold, but this is seldom the case. And even if this were the case, a responsible board of directors would require a thorough economic analysis before committing this level of funding for a project.

A mineral property with no current mineral resources or mineral reserves has been described by the Canadian National Instrument 43-101 policy as an "early stage exploration property" (OCS 2011). This is the case with the Idaho-Maryland property's latest 43-101 compliant technical report (Rise Gold 2017).

A mineral resource is a concentration or occurrence of solid material of economic interest. A mineral reserve is the economically mineable part of a measured and/or indicated mineral resource (ICMM 2013). The figure below has presented in approximately this same format for quite some time as a way to illustrate how the concepts of mineral resource and mineral reserve are related – technically, economically, and legally.

**Grp 7-175**

***Classification of Mineral Resources & Reserves (ICMM 2013)***

**Grp 7-176**

Rise Gold does not have enough drill samples to satisfy the requirements to meet any of the mineral resource or reserve definitions described in the Classification of Mineral Resources & Reserves. This same lack of an adequate number of drill samples also results in the lack of data required to adequately characterize the geochemistry of the waste rock and tailings that will be produced, or to supply test data on the leachate from this waste that would allow modeling of potential impacts to surface water.

Page #3

**Geochemistry of the waste rock**

The projected waste rock geochemistry analysis is summarized in the EIR Appendix K.2: Groundwater Hydrology and Water Quality Analysis Report for the Idaho-Maryland Mine Project Nevada County, California, EMKO Environmental, February 2021.

In Table 4-5 (below) from Appendix K.2, it is predicted that the 96% of the waste rock will produced will be Meta-Andesite.

***Table 4-5 Estimated Daily Barren Rock Production***

| Material Type | Tons per Day | Percent of Material Produced |
|---|---|---|
| Meta-Andesite | 481 | 96 |
| Altered Meta-Andesite | 12 | 2 |
| Diabase | 5 | 1 |
| Serpentinite | 2 | 1 |
| **TOTAL** | **500** | **100** |

Rise completed 19 drill exploration drill core holes, totaling 67,500 linear feet, from 2017-2019. From this drill core, Benchmark Resources collected six drill core samples that it used to characterize the geochemistry of the waste rock. These samples are listed in Table 4-6.

Meta Andesite, which constitutes 96% of the waste rock to be mined, was taken from three intervals of drill core – samples MA-1, MA-2, and MA-3. Sample MA-1 was from the near surface rock 167' - 177' below the drill level, so it not representative of most of the Meta Andesite that will be produced from mining, which will occur at much greater depth. As a result, the geochemical predictions for approximately 96% of the waste rock to be produced comes from one 10-foot interval of drill core (Sample MA-2 from 3959.7 ' to 3969.7'), and one 1-foot sample (MA-3 from 3265' to 3266').

***Table 4-6 Core Samples Collected by Benchmark Resources***

| Sample Name | Description | Date | Time | Bag # | Hole # | Elevation Interval |
|---|---|---|---|---|---|---|
| MA-1 | Meta Andesite/Porphyrite | 29/10/2019 | 10:45 AM | Y973551 | I-19-13 | 167'-177' |
| MS-1 | Meta Sediment/Porphyrite | 29/10/2019 | 11:00 AM | Y973560 | I-19-13 | 1,067'-1,077' |
| MA-2 | Meta Andesite/Porphyrite | 29/10/2019 | 11:05 AM | Y973594 | I-19-13 | 3,959.7-3,969.7 |
| MAA-1 | Meta Andesite Altered/Porphyrite | 29/10/2019 | 11:20 AM | core box | I-19-13 | 3,357'-3,360' |
| S-1 | Serpentinite | 29/10/2019 | 11:25 AM | core box | I-18-11 | 4,725.6'-4,725.7' |
| MA-3 | Meta Andesite Altered/Porphyrite | 29/10/2019 | 11:45 AM | core box | I-18-10 | 3,265'-3,266' |

Another way to describe this is that the geochemical characterization of the 2 million tons of waste rock produced during the first 11-years of mining, and nominally the waste rock production from the entire 80-life of the proposed permit, is represented by these two samples, which come from a total of 11 feet of drill core.

Page #4

***Australian Guidance on Sample Numbers (adapted from Australian Government Department of Industry, Tourism and Resources, 2007 (GARD Guide Table 4-5)***

| Mine Phase | Number of Samples | Description |
|---|---|---|
| Exploration | (1) Prospect Testing – Include sulphur in list of elements being analyzed for all samples tested; include the full range of pathfinder elements as defined by ore deposit/exploration model; collect and record mineralogical data as per exploration/ore deposit model; where the geology of the deposit is known include static testing of at least 3 to 5 representative samples of each key material type (i.e., lithology, alteration type); analysis of ground water and surface water for acidity and representative pathfinder elements.<br>(2) Resource Definition – All samples tested for sulphur and representative samples tested for mineralogy as per ore deposit model. **Static testing of at least 5 to 10 representative samples of each key material type. *(emphasis added)***<br>Collect groundwater and surface water data. Surface water and groundwater analysis to include acidity as well representative metal ions.<br>All testing to include QA/QC samples. | By the end of the resource definition phase, there should be adequate information to accurately characterize the ARD potential of the ore body (high and low grade), although further test work will normally be required to characterize the ARD potential of waste rock and ore and hence tailings. |
| Pre-Feasibility | **Static testing of several hundred representative samples of high and low grade ore, waste rock and tailings**, the number dependent on the complexity of the deposit geology and its host rocks. ***(emphasis added)***<br>All drillhole samples analyzed must include sulphur analysis and identified representative metal ions. Sampling density is dependent on complexity of ore deposit and host rock geology interval of representative drill holes but should be restricted to single rock units or lithologies - include minimums.<br>**Kinetic testing of at least 1 to 2 representative samples of each material type. *(emphasis added)***<br>Surface water and groundwater analysis to include acidity as well as pH, EC and representative metal ions, including Al, Fe, Mn.<br>All testing to include QA/QC samples. | Where required, the number of samples must be sufficient to populate a "resource" block model of the ore and host rocks that will be affected by mining with a reliable distribution of NAPP[1] data (e.g., acid producing potential (APP), sulphur and acid neutralizing capacity (ANC) (or NPR data) on ore, waste rock and wall rock. |
| Mine Planning, Feasibility and Design | Where required, additional static testing as required for block waste resource model refinement – **increase density of NAPP (or NPR) characterization. *(emphasis added)***<br>Inclusion of confirmatory testing (e.g., NAG testing for comparison to NAPP (i.e. APP, or sulphur, and ANC) for metalliferous deposits; and mineralogy or NPR values).<br>Continuation of kinetic testing.<br>Upgrade drillhole database and waste resource model for new ore positions.<br>All testing to include QA/QC sample(s). Apply QA/QC to all analyses, not only ore. Include wall rock. | Data set must be sufficient to assess ARD potential to support a management plan. If data are insufficient, additional testing will be required. |

Page #5

The widely accepted source of guidance for determining the number of samples for acid-drainage/metals-leaching prediction is the Global Acid Rock Drainage Guide (GARD 2018), published by the International Network for Acid Prevention. The GARD Guide has adopted the Australian Guidance on Sample Numbers for determining the number of samples needed to determine acid-drainage/metals-leaching potential (GARD Guide Table 4-5).

The number of samples used to predict the leaching potential of the tailings and waste rock for the proposed Idaho-Maryland Project does not meet even the lowest level of these criteria. The number of samples analyzed for this proposal would not even meet the requirements for the Exploration stage of sampling, let alone the Mine Planning, Feasibility and Design phase, which is the level of development being proposed for the Idaho-Maryland Project.

**3.7 Project Components– Water Treatment**

Grp 7-177

There is no discussion, or disclosure, of the operational water quality treatment needs or processes. The EIR merely requires that the applicant apply to the Regional water Quality Control Board for a discharge permit. The water quality discharge that will be required by the discharge permit should be disclosed in the EIR so that the public is able to assess and comment on the potential impacts. To simply assert that water quality standards will be met is not sufficient for reviewers to assess either the adequacy of the water treatment methods proposed, or the adequacy of the standards proposed for the discharge permit.

This completely circumvents any discussion or analysis of what the contaminants of potential concern might be, what contaminants would be monitored, what treatment methods are available, and where monitoring would take place. This information should all be disclosed in the EIR.

Grp 7-178

In addition, a Monitoring Plan should be included. The Monitoring Plan should incorporate all elements of monitoring, including surface water, ground water, air, and noise sampling. Sampling locations, frequencies, and constituents should be disclosed/discussed in the Monitoring Plan, and summarized in the EIR.

**3.7 Project Components – Backfill**

Grp 7-179

It is noted that approximately 500 tons/day of tailings will be backfilled into the mine as cemented paste. The technical details of the process are contained in "Desktop Study of Cemented Paste Backfill, ITASCA Denver, Inc. February 24, 2020." In this report it is noted that no tests on the leaching characteristics of tailings have been performed, but that testing would be done when a cement had been selected. Even though the backfill is unlikely to turn acidic, the potential for neutral leaching of contaminants like arsenic need to be investigated.

The answers to several critical questions that should be addressed in Chapter 3 of the EIR are: (1) the grind size of the tailings used for backfill; (2) the type and amount of cement to be used; and, (3) the results of leach tests on the backfill.

This information should have been available for the EIR, and is another data gap in the EIR.

**3.7 Project Components – Engineered Fill Transport**

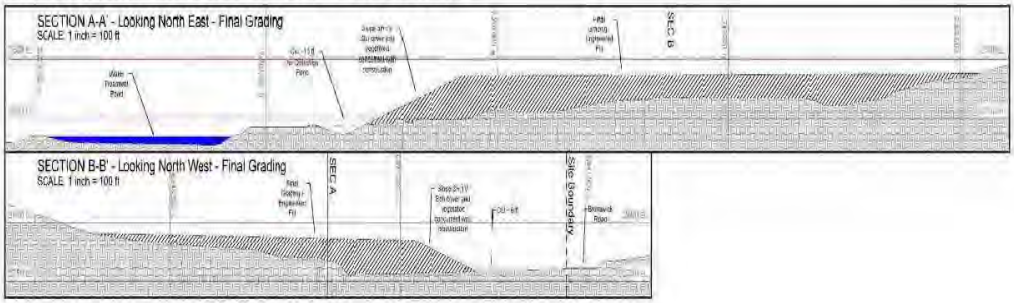
Even though this is nominally the section about the transport of the waste material, most of the technical information on the Engineered Fill is presented here.

Grp 7-180

The mine waste that is not backfilled into the mine will consist of 50% tailings (rougher tailings from flotation separation in the mill), and 50% waste rock from the mine. Approximately 4 million tons of waste would be placed at two sites near the mine during the first 11-years of mining. The number of samples utilized in the leach tests of this waste is not sufficient to properly characterize the contaminants

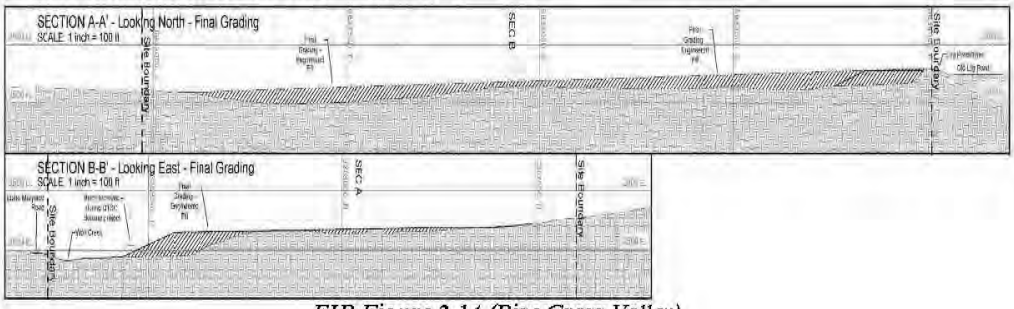
Page #6

that may be leached from the waste. Comparing the number of samples cited in the EIR to the sampling guidelines of the GARD Guide demonstrate the insufficiency of the existing tests.



In addition to testing for the contaminants that may come from the waste, as the term "engineered fill" implies, this will be an engineered mine waste facility. The EIR, and its supporting documents, imply that the required engineering analysis will be done at some future time, but provide virtually no engineering analysis or design specifications for these waste facilities as a part of the EIR.

It is stated in the EIR that, "*Engineered fill would continue to be placed, graded, and compacted in a series of lifts …*" The only drawings of the cross sections of the waste facilities in the EIR are from Rise Grass Valley, not an engineering company, and seems to show the mine waste being deposited as end-dump layers that cannot be compacted to generate further stability, not horizontally-deposited layers that could be compacted.



The new mine waste will be placed on top of portions of existing mine waste, which could provide a plane of weakness that could provide an additional failure plane for the significant weight of rock that will placed on top of it. The Brunswick facility is projected to be up to 90 feet in height, and the Centennial facility up to 70 feet high.

**Grp 7-181**

BRUNSWICK INDUSTRIAL SITE - SECTIONS

CENTENNIAL INDUSTRIAL SITE - SECTIONS

*EIR Figure 3-14 (Rise Grass Valley)*

Page #7

There is no technical report to provide the detail needed to evaluate the geotechnical viability and safety of these facilities. The potential for this waste to fail under static or seismic loading needs to be professionally evaluated by a qualified engineering contractor. It would be inappropriate to issue a permit for the construction of these waste facilities without proper engineering analyses. To illustrate what could happen, the picture in Photo 1 comes from a waste rock pile at a Nevada mine that failed due to inadequate engineering. While not catastrophic, such failures can cause significant environmental and economic damage.

***Photo 1: Waste Rock Dump Failure at the Gold Quarry mine (2005)***

The seismic reports discussed in the Geology section of the EIR are not up to date, and even if updated would not meet the requirements for a probabilistic seismic site analysis. Mine waste facilities must be designed to withstand much larger seismic events than required by typical seismic building codes because of the long expected life of the water facilities. According to information provided in the Brunswick and Centennial Industrial Site Geotechnical reports (EIR Appendices H.1 and H.4), a probabilistic and/or deterministic seismic assessment has not been done for the Idaho-Maryland site.

**Grp 7-182**

In the geotechnical report for the Centennial Industrial Site the mine waste to be used as engineered fill is described as; "*We understand that proposed foundation structures will be constructed on import fill material that will primarily consists of medium dense granular soil composed of silty or clayey sand/gravel, with possible rock fill at depths.*" The term "medium dense granular soil composed of silty or clayey sand/gravel" is not an adequate description of the tailings. Tailings, at a 75 um grind size, the most likely choice for grind size based on the flotation recovery testing done by McClelland Labs, are termed "silt" (see EIR Appendix H.4, Table 5.1-1, Particle Size Gradation, Historical Sand Tailings).

Page #8

**Grp 7-183**

With an equal ratio of tailings to waste rock in the engineered fill, not only is a careful analysis of the geotechnical properties of the tailings important, and currently lacking, but how these two fill sources are mixed is also critical, since the tailings and waste rock have very different geotechnical properties. These analyses are lacking in the EIR and its supporting technical reports.

**Grp 7-184**

In the EIR, it is also proposed that an alternative for placing the mine waste in the proposed facilities is selling the waste in the local marketplace as fill material. There are several issues that make this proposal unlikely. First, there is liability associated with mine waste. Even if the waste is purported to be contaminant-free, and this waste is associated with mining sulfide mineralization that can release metal contaminants, it is seldom possible to guarantee that all of the waste will be contaminant-free. According the laboratory analysis for the six waste rock samples analyzed for Acid-Base Accounting, the sulfide sulfur content of the waste rock varies from 0.04 - 1.78 % Sulfide Sulfur (EIR Appendix K.2, EMKO 2021, Table 4-8 Tailings & Barren Rock Samples - ABA Results). There is significant variability in the amount of sulfide sulfur, and significant amount of sulfide sulfur (1.78%), recorded in the very limited number of waste rock samples tested. If any of the waste sold as clean fill should cause a problem, the sellers of that material, and the company that produced that material, would likely be legally liable. Just the possibility of legal entanglement keeps virtually all mining companies from selling its waste rock or tailings, and is very likely to make it very difficult to find an independent distributer that is willing to assume this risk.

**Grp 7-185**

A second issue is one of logistics. The mine waste is produced at a constant rate – 1,000 tons per day, 365 days/year, for the life of the mine. Markets for fill material are typical episodic. For example, there is much more fill material placed during the summer than during the winter. In order to handle surges in the demand for fill material, temporary storage for a significant amount of material would be required by a vendor of this material. If the mining company is going to provide this service itself, then the storage facility should be evaluated as a part of the mine proposal. If the material is to be sold to an independent user, then the viability of that operation should be demonstrated with at least a contract that someone is willing to accept 1,000 tons/day of mine waste.

**3.7 Project Components – Reclamation Plan**

Most reclamation plans submitted as a part of a mine proposal are largely conceptual in nature, including the reclamation plan accompanying this EIR. However, for those tasks that can be clearly identified as being necessary for mine closure, these tasks should be described with enough detail that the engineering feasibility and cost can be analyzed.

In order to protect the public from incurring the costs associated with an unplanned mine closure, or bankruptcy, the funds should be available to public agencies that are sufficient for those agencies to take over and complete reclamation of the mine, and to perform any water treatment that may be required.

**Grp 7-186**

At the Idaho-Maryland Mine, it is known that mine openings must be closed, drains must be prepared to collect the seepage that has been coming from the mine, and that will presumably resume after mine closure, and that the mine waste facilities can be closed and safe configuration. However, there are no reclamation engineering specifications, work plans, or cost estimates made for the EIR.

The potential costs for post-closure water treatment, if required, should also be included. However, there is insufficient information on seepage water quality to conduct this analysis.

Financial Assurances for mine closure runs tens to hundreds of millions of dollars, so ignoring these costs puts taxpayers at significant risk of miscalculation at a later date. Because these sums are so substantial, the public should be informed about these costs, and how the costs were estimated.

This is a significant omission in the EIR.

Page #9

**4.8.2 Existing Environmental Setting – Groundwater Occurrence in Mine Workings**

**Mine Flooding and Worker Safety**

In the discussion of the Union Hill Mine, it is noted, "*The Union Hill Mine workings are within 95 feet to 180 feet of workings of the Brunswick Mine at three to four different levels. During the post WWII period, the combined Idaho-Maryland Mine workings were completely dewatered. In 1956, the water level at the Union Hill Mine was reported to be within 20 feet of the top of the shaft, suggesting that the complete dewatering of the adjacent mine workings resulted in no more than 10 to 20 feet of water level decline in the Union Hill Mine.*"

**Grp 7-187**

There are two important points to note in this discussion, (1) the Union Hill Mine is very close to the Idaho-Maryland at several levels; and, (2) there has been a possible weak hydraulic connection between the two mines, which is only logical.

The EIR notes that the Union Hills Mine will not be dewatered. The EIR suggests there is no significant hydraulic connection between the mines, but the discussion from the EIR quoted above suggests there could be some connection, and what is not known is whether this hydraulic connectivity could increase in the future.

There is no discussion in the EIR of the potential impacts for the Idaho-Maryland Mine if flooding were to occur during mining. From ITASCA Figure 2-3 (attached as the last page of this document), it can be seen there are extensive abandoned mine working above and adjacent to the Idaho-Maryland mine that will remain flooded after the Idaho-Maryland is dewatered.

If a conduit between these two mine were to open, for instance due to the widening of a fracture related to blasting vibrations or a seismic event, the flood of water into the Idaho-Maryland could be rapid and catastrophic for anyone working in the mine.

This issue must be thoroughly addressed before anyone is permitted to enter the dewatered mine.

**4.8.4 Impacts and Mitigation Measures – Water Within Underground Mine Workings**

**Geochemistry of the tailings**

Even though this is nominally the section about the underground mine water, most of the technical information on the geochemistry of the tailings samples is presented here.

Approximately 50% of the mine waste, also referred to as "engineered fill", disposed on the surface will be tailings. The geochemistry of these tailings is important because meteoric waters will infiltrate through the waste, and any leachate products will end up in groundwater, and potentially surface water.

**Grp 7-188**

Tailings produced in the milling process are generally homogeneous because the physical and chemical processing of the ore remains relatively constant, and the ore is typically blended to maintain a consistent ore grade to facilitate gold recovery. Because of this, fewer tailings samples than waste rock samples are required for leach testing, but those testing samples must be representative of the tailings that will be produced during mine operation.

While Appendix K.2 states that the tailings samples were generated from a "46 kg metallurgical sample". The ore sample used to create the four tailings samples contained 1.6% Sulfur (EIR 2021, p. 4.8-46). The four tailings samples had a sulfur content of 0.06 – 0.12% Sulfur (EIR 2021, p. 4.8-46), with Net Neutralization Potential greater than 100 for all samples (EIR Appendix K.2, EMKO 2021, Table 4-8 Tailings & Barren Rock Samples - ABA Results).

The drill hole intervals this material came from is not stated in the EIR, nor is the time when the metallurgical sample was generated. Again, if an NI 43-101 compliant report that reported a mineral

Page #10

resource and/or reserve were available, this basic information would have required and would have been available for the EIR.

In Appendix K.2, EMKO notes that the four samples are of different grind sizes. The size of the tailings particles could have an effect on the rate of leaching. Smaller grain size leads to more rapid leaching of contaminants. Based on the results of the metallurgical testing, a final grind size is generally selected before geochemical testing is done, but a final grind size has not been selected for this project. The different grind sizes of the tailings could have an unquantified effect on the leach testing of the tailings samples.

**Grp 7-189**

Because the size specification has geotechnical and geochemical implications for both the tailings disposed on the surface, and cemented backfill in the mine, the size specification needs to be disclosed in the EIR. The limited test results available from preliminary tailings tests are not sufficient to make long-term predictions for the geotechnical stability or water quality implications of the tailings.

The method selected for leach testing the tailings and waste rock used distilled water, which is the least aggressive of the leach testing methods. For mining waste, waste rock and tailings, short-term tests typically use a weak acid solution for leach testing in order to simulate the generation of some acid in the waste due to sulfide decomposition. Long-term leach testing, which runs for months rather than hours or days, typically uses distilled water, because natural sulfide decomposition and the accumulation of oxidation products has sufficient time to stabilize.

***From Table 4-7 Tailings & Barren Rock Samples - Total Metals and DI-WET Results***

| Constituent | Test Type | Units | Tailings Samples | | | | Rock Samples | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Manganese | Total | mg/Kg | 1000 | 1010 | 990 | 994 | 604 | 747 | 1230 | 311 | 696 | 176 |
| | DI-WET | mg/L | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 | <0.01 |
| **GENERAL CHEMISTRY PARAMETERS** | | | | | | | | | | | | |
| Nitrate | DI-WET | mg/L | 0.06 | 0.08 | 0.28 | 0.24 | <0.02 | <0.02 | 0.05 | <0.02 | <0.02 | <0.02 |
| Sulphate | DI-WET | mg/L | 8.40 | 6.30 | 8.50 | 8.70 | 3.3 | 1.4 | 6.60 | 1.9 | 1.1 | 2.8 |

**Grp 7-190**

In reviewing the leach test results from Appendix K.2, Table 4-7: Tailings & Barren Rock Samples - Total Metals and DI-WET Results, the following observations are noted:

- Aluminum levels in the leachate are high. Even though the measurement was probably done as Total aluminum, these levels suggest that aluminum leaching could be an issue, and that Dissolved aluminum should be monitored.

**Grp 7-191**

- There is antimony present, and the water quality standard for antimony is low. Waste rock sample S-1 shows a level of antimony that is well above the water quality standard. Even though there is only a relatively small amount of S-1 rock in the waste, antimony should be monitored.

**Grp 7-192**

- Arsenic is measured at about 20% of the water quality standard, and is known to be an issue with the existing mine waste. Arsenic could become an issue if localized acidic conditions, or longer exposure time, drive the oxidation reactions.

Page #11

**Grp 7-193**
- Copper being detected at levels that could exceed water quality standards, but the measurement level for the sampling was too high, so we don't know enough about what is going on with copper.

**Grp 7-194**
- Iron and Manganese are both know to be present in existing mine water and the mine waste at levels that exceed water quality standards, but they are not showing elevated levels in the test data. This strongly suggests that the oxidation taking place in the mine itself, and in the mine waste on the surface, is more aggressive than that being simulated in the leach tests using distilled water.

**Grp 7-195**
- Nitrate, a residual from blasting, will almost certainly be present at levels significantly higher than projected in these tests.

**Grp 7-196**
- Similarly, sulfate will be higher than projected once the waste has time to oxidize.

**Grp 7-197**
- An important constituent, sulfide-sulfur, is not reported on a per-sample basis

**Grp 7-198**
In the summary of the report (Appendix K.2), EMKO notes that Potential Contaminants of Concern include ammonia, arsenic, hexavalent chromium, iron, manganese, pH, total suspended solids, TDS, and cis-1,2-DCE. To this list, I recommend adding antimony, copper, and nitrate.

**Grp 7-199**
Leach tests for the paste backfill also need to be completed. It is not appropriate to grant a mining permit that allows the use of this backfill without evaluating the potential long-term effects on water quality.

**6.3 Selection of Alternatives – Alternatives Considered in this EIR**

The mining project as proposed in this EIR has a fundamental lack of information on the economic viability of the mine, and potential environmental impacts related to geochemistry and water quality.

**Grp 7-200**
The data submitted in support of this EIR is only sufficient to support an application for dewatering the mine, and for underground exploration drilling. This would provide not only the information that will be required to perform a preliminary economic analysis of the orebody, but would also supply the samples needed for geotechnical and geochemical testing, and for water quality modeling.

The EIR should analyze an Alternative that provides for dewatering and underground exploration. That is the only Alternative that the information provided in this EIR will support.

Thank you for the opportunity to comment on this Draft EIR.

Sincerely;

David M. Chambers, Ph.D., P.Geop.

## GROUP LETTER 7: RALPH SILBERSTEIN, COMMUNITY ENVIRONMENTAL ADVOCATES FOUNDATION

### Response to Comment Grp 7-1
This comment is introductory in nature. The comment alleges that the project would cause long-lasting environmental impacts and that the EIR is inadequate. The commenter's specific comments are discussed in the following responses to comments.

### Response to Comment Grp 7-2
Please see Master Response 4 relating to the Separate Centennial Project.

### Response to Comment Grp 7-3
Please see Master Response 24 – Project Construction Schedule. As discussed in Master Response 24, the project assumes a compressed construction schedule where many activities overlap to provide the most conservative estimate of air quality, traffic, noise and other impacts. An increase in the duration of construction activities and/or the completion of activities sequentially would serve to reduce environmental impacts in many areas. As such, the approach taken by the EIR overestimates impacts as compared to a longer construction schedule with less overlapping activities.

### Response to Comment Grp 7-4
Please see Master Response 24 – Project Construction Schedule, and Response to Comment Grp 7-3 above.

### Response to Comment Grp 7-5
Please see Master Response 11 – Engineered Fill Utilized in Local and Regional Construction Markets.

### Response to Comment Grp 7-6
For responses to the commenter's referenced ASUR Plan Analysis, please see Responses to Comments Grp 7-103 through Grp 7-137.

The comment states that the DEIR does not include any evidence that asbestos levels will not exceed applicable thresholds set forth in the asbestos management plan. However, prior to underground gold mining, intensive planning efforts will be conducted as required under the ASUR plan and as required to meet state and federal regulations and achieve safety, environmental, and economic goals. Please see Section 6.0 of the ASUR Plan (Appendix E.2 of the EIR). Underground mine planning, as required in the ASUR plan, includes exploratory drilling, geologic mapping, material logging, and testing. These same processes also ensure future mining operations avoid and manage rock types that may contain naturally occurring asbestos to ensure that applicable thresholds are not exceeded. (Id.) In other words, the mandatory mine planning that is required by the DEIR in the ASUR Plan will provide information to the mine operator on asbestos content of rock prior to mining that area. That information can then be used to avoid areas, if any exist, with asbestos content that would make it infeasible to comply with the 0.01% asbestos content limit required by the ASUR Plan.

Additionally, the Health Risk Assessment is based on conservative assumptions, such that the analysis overestimates health impacts rather than underestimates those impacts. Please see Master Response 22 – Conservatism used for Asbestos Assumptions

Based on these conservative assumptions, the DEIR concludes that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

## Response to Comment Grp 7-7

The commenter asserts that asbestos testing could take up to two weeks before results are known, which could result in impacts to workers prior to obtaining results, as a result of contact with stockpiles and mined material with higher asbestos content. The commenter also states that material will be stockpiled before testing resulting in undisclosed dust and asbestos impacts; however, the commenter's presumption is incorrect as the mined material will be stored in enclosed silos or bins, not in stockpiles. Testing of material will be done in advance by underground drilling rigs, such that the asbestos content of the material to be mined will already be known prior to mining. This is a standard component of modern underground mine planning, and was made an explicit requirement of the ASUR Plan, which will be required under a Condition of Approval. As such the mine operator will know the asbestos content in any rock that is intended to be mined, well before that rock is actually removed, and the workers should not be exposed to rock with unexpected high values of asbestos.

As discussed on page 4.3-61 of the EIR, the average asbestos content of the total mined material is of primary concern given that asbestos does not have established acute noncancer effects. The purpose of TEM testing in the ASUR Plan, including testing of aboveground rock in the silos, is not to control the fate of the rock and tailings after it reaches surface (that is the purpose of the PLM testing). Rather, the TEM testing, including testing of aboveground rock in the silos, is done to verify that mine planning is effectively minimizing the potential for public exposure to airborne asbestos from the project. Therefore, the two-week time to receive results from TEM testing of materials at surface allows the achievement of the goals of the ASUR Plan.

In addition to the testing procedures that will be implemented as part of the ASUR Plan, the protection of workers in underground mines from asbestos exposure is also governed by MSHA regulations as discussed on page 4.3-61 and 4.3-20 of the EIR. Accordingly, mine works have redundant layers of protection from asbestos exposure.

Finally, Mitigation Measure 4.3-2 of the EIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

## Response to Comment Grp 7-8

Please see response to referenced Baseline comment in Response to Comment Grp 21-109. In addition, please see Master Response 9 – Historical Mine Waste at Centennial Site.

## Response to Comment Grp 7-9

Please see Master Response 8 – Mine Waste Characterization. The commenter implies that the amount of testing performed on rock cores obtained from the project site is inadequate but does not explain why the number of samples analyzed is not sufficient for CEQA analysis other than a general assertion that more sampling could be done. Additional samples may be required to achieve "engineering level detail" on specific aspects of the rock types expected underground; however, the volume of samples provided is expected to be representative of the overall rock types, and further, engineering level detail is not required in an EIR. (Dry Creek Citizens Coalition v. County of Tulare (1999) 70 Cal.App.4th 20, 26.) Additionally, the DEIR imposes mitigation measures that require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Quality Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). The CVRWQCB requires additional waste characterization as part of approving WDRs and also requires ongoing water quality monitoring during the implementation of WDRs to ensure that no water quality impacts will occur. The commenter also asserts that the chain of custody processes are not sufficient, but does not identify any particular issue. Note that the applicant will be required to adhere to any chain of custody requirements applicable for submittal of a RoWD and obtaining WDRs from the CVRWQCB prior to operations.

## Response to Comment Grp 7-10

Please see Response to Comment Grp 7-9 above and Master Response 8 – Mine Waste Characterization. The DEIR concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measures 4.8-1(d) and 4.8-1(e) to address these potential impacts. Additional core samples and additional leachate tests would not alter the significance of the impact identified in the DEIR, as it is already considered potentially significant, and would not alter the requirements for mitigation which require additional testing as part of the RoWD and WDR process.

## Response to Comment Grp 7-11

Please see Response to Comment Grp 7-9 above and Master Response 8 – Mine Waste Characterization. The locations and descriptions of samples and other geological data are provided in Appendix K.2 of the DEIR. Exploration drill logs are not necessary for the analysis.

## Response to Comment Grp 7-12

The commenter states that water samples from the existing mine drains should be considered to define water treatment criteria rather than water sampled from the New Brunswick shaft. However, once mine dewatering commences the flow of water through the mine workings would be altered from its current condition with water pumped up the New Brunswick shaft rather than flowing through the historic mine workings to the current mine drains. As such, the water from the mine drains is not likely representative of water that would be encountered during dewatering prior to treatment and discharge during mine dewatering. However, the elevated arsenic levels in the drain versus the New Brunswick shaft have been noted in the EIR (page 4.8-21) and the water treatment plant is designed to treat arsenic in mine water if present during mine dewatering. Please see Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 7-13

The commenter alleges that the water quality in the nearby Empire Mine is evidence that the project will create acid rock drainage, and that the commenter prefers a different method for

testing the rock found within the mine. However, the geology in the project area is different from that in the Empire mine due to carbonate minerals in the project host rock (see page 13 of Appendix K.2), which results in the lower potential for acid rock drainage; thus, the method used for testing rock is appropriate for this mine. Further, mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRWQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). The CVRWQCB will determine the appropriate method of rock testing for the purposes of developing WDRs. See Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 7-14

See Master Response 8 – Mine Waste Characterization. Based on the geology of the rock encountered in the core drilling at the project site, and testing of those samples, acid rock drainage is not expected. (DEIR p. 4.8-50.) Nonetheless, the EIR has concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measures 4.8-1(d) and 4.8-1(e) to address these potential impacts and reduce the impact to less than significant. The purpose of the Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board is to ensure the effluent from mine waste does not impact water quality. Further testing will be required as part of the RoWD and WDR process as required by Mitigation Measures 4.8-1(d) and 4.8-1(e) such that any impacts will be mitigated. WDRs for the project will require monitoring and reporting to ensure compliance.

## Response to Comment Grp 7-15

The commenter asserts that impacts to water quality must be considered significant and unavoidable. However, testing of rock from the project site and required mitigation measures provide substantial evidence that water quality impacts will be reduced below a level of significance. See Master Response 8 – Mine Waste Characterization and Responses 19-9 to 19-14 above. Contrary to the commenter's assertion, page 4.8-50 of the DEIR does not discuss "an expedited General Order". It discusses the RoWD and WDR requirements for mine waste which are required under Mitigation Measures 4.8-1(d) and 4.8-1(e).

Based on the testing of rock material from the project site, the proposed project would likely produce mine waste with lower sulfide and metal content than those produced historically, and the historic mine waste has been determined to be Group C mining waste from which any discharge would be in compliance with the applicable water quality control plan, including water quality objectives other than turbidity. Please see Master Response 9 - Historical Mine Waste at Centennial Site.

As discussed on page 4.8-50, California Waste Extraction (WET) testing was performed on samples of mine materials and the results of these tests suggest the engineered fill (barren rock and sand tailings) will be a Group C mining waste. However, the determination of waste classification is conducted through the RoWD and WDR process required by Mitigation Measures 4.8-1(d) and 4.8-1(e). Extensive testing and sampling would be conducted for the RoWD and before approval of the WDR. See Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 7-16

Please see response to referenced Baseline comment. Please see Response to Comment Grp 21-124.

## Response to Comment Grp 7-17

For responses to the commenter's referenced HRA Critique, please see Responses to Comments Grp 7-138 through Grp 7-154.

The dispersion model in the Health Risk Assessment used the most appropriate data for the HRA. Please see Master Response 17 - Meteorological Data Used in HRA.

## Response to Comment Grp 7-18

For responses to the commenter's referenced Sampling Procedures, please see Responses to Comments Grp 7-155 through Grp 7-172.

Please see Master Response 21 – Conservatism of Silica Assumptions and Master Response 22 – Conservatism used for Asbestos Assumptions. The assumed crystalline silica content and modeling of respirable silica is conservative and overestimates the relevant exposure in any situation. Therefore, sampling of materials for crystalline silica content is not required.

## Response to Comment Grp 7-19

The commenter states that the DEIR should include asbestos mitigation as well as mitigation for impacts associated with TACs, and silica. The DEIR analyzes impacts associated with asbestos, TACs and silica and includes mitigation measures to reduce impacts to less than significant. (See DEIR, Chapter 4.3.) Please see Master Response 22 – Conservatism used for Asbestos Assessment. Mitigation Measure 4.3-2 of the EIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

The assumed crystalline silica content and modeling of respirable silica is conservative and overestimates the relevant exposure in any situation. Please see Master Response 21 – Conservatism of Silica Assumptions.

The commenter also questions the 30-year exposure duration assumption included in the Health Risk Assessment (HRA) prepared for the project. Notably, the 30-year exposure assumption is based on the Office of Environmental Health Hazard Assessment's (OEHHA) Air Toxics Hot Spots Program Risk Assessment Guidelines – Guidance Manual for Preparation of Health Risk Assessments (2015) (OEHHA Guidelines), which states that:

> OEHHA recommends that an exposure duration (residency time) of 30 years be used to estimate individual cancer risk to the maximally exposed individual resident (MEIR)… OEHHA also recommends that the 30-year exposure duration be used as the basis for public notification and risk reduction audits and plans.

Based on data from the U.S. EPA, the 30-year residency is considered a high-end estimate of residency time. As standard practice, the duration of exposure is based on 30-year sensitive receptor residency rather than the life of the project. Further, additional conservatism is layered into OEHHA's recommendations that were incorporated into the HRA prepared for the project, including the assumption that exposure at all sensitive residential receptors would begin in the 3rd trimester of gestation and that the baby would be born and would grow through childhood and adulthood at the same home for the next 30 years. This scenario is unlikely to happen, yet it captures a conservative situation for health risk assessment purposes.

## Response to Comment Grp 7-20

The commenter disagrees with the methods and conclusions of the groundwater model. The groundwater model used for the DEIR was calibrated on historic groundwater inflows into the mine, the current and historical water level in the Union Hill Mine, the current water level in the New Brunswick Shaft, ground measured water levels in domestic water wells in the area and base flow rates of Wolf Creek and South Fork Wolf Creek.

The commenter asserts that the water level measurements used to calibrate the groundwater model are insufficient. However, the groundwater model is calibrated to measured water levels in domestic wells and not just the water level in the Union Hill Mine. Itasca simulated pre-historical mining conditions (before any mining had taken place). Itasca calibrated the model against water levels measured in wells outside of the mine area. (Section 4.5). Using the simulated groundwater from the pre-historical mining condition, Itasca calibrated the model using the known inflow rates and underground mine workings from two periods of mining. The Idaho mine in 1918 and the entire connected Idaho-Maryland-Brunswick mine in 1956. The model was also calibrated against the known level of water in the Union Hill mine in 1956. (Section 4.6 pages 21-22). The drain nodes for the mine workings were turned off and mine voids were simulated with a zone of high K and the drains along Wolf Creek (which currently drain the mine) were added at their known elevation. Please see Memorandum Itasca Groundwater Model attached to the Final EIR as Appendix O. The model was then compared against water levels measured in wells in the mine area. The model was found to be correctly calibrated to the measured water levels. (Section 4.5 page 22).

As stated on page 4.8-41 of the DEIR, the county's independent expert West Yost found that the groundwater model was acceptably calibrated pursuant to industry practices. Accordingly, the DEIR contains concurrence of multiple experts on the suitability of the groundwater model and as such, constitutes substantial evidence of the significance conclusions.

## Response to Comment Grp 7-21

Please see Response to Comment Grp 7-20 which describes the calibration of the groundwater model. The current flow rate of mine water from the drains was not used for the calibration of the groundwater model because the preferential pipe flow in the mine workings is not simulated in the model and the purpose of the model is to calibrate to "current" 2019 groundwater levels, based on measurements taken from 1994 through 2007, and the current water level in the mine which is controlled by the drain outlet elevations. Additionally, there could be additional preferential recharge from surface runoff through mine workings reporting to the drains. This extra recharge, not related to groundwater flow, is not quantifiable and could result in inaccurate calibration of the groundwater model

The outflow data of the drains from previous studies is similar to current measurements. Please see Response to Comment Grp 7-68.

The commenter suggests that more measurements of water level in the New Brunswick shaft are needed. However, historic and recent observation show that additional measurements are not necessary, as the water level in the Brunswick shaft does not vary significantly over time because groundwater in the Brunswick mine, as observed in the New Brunswick shaft, has a pathway to flow to the drains along Wolf Creek through tunnels in the B2300 and B3280 levels. (See page 4.8-44 and Figure 4.8-7 of the DEIR.)

## Response to Comment Grp 7-22

The current flow rate of mine water from the drains was not used for the construction of the groundwater model and is not necessary for the groundwater modelling method used in the DEIR. Accordingly, the commenter's request for inflow/outflow data is not relevant to the groundwater model and the assessment of groundwater impacts. Please see Response to Comment Grp 19-20 and Grp 19-21.

## Response to Comment Grp 7-23

The commenter states that data from private wells is old and is limited to a few years without usage data provided. Contrary to the commenter's assertion, water level data has been collected for many years over a period spanning two decades. As stated on page 26 of Appendix K.2, monitoring of water level in wells for up to 79 wells was undertaken from 1995-2001 and 2003-2007. As noted in the report, no long-term increasing or decreasing trends are observed in the data. Therefore, the age of the sample data does not limit the usefulness of this data. Consumptive water uses from individual wells are not considered because of the lack of consumptive-use data and the fact that consumptive groundwater well water use is small relative to regional groundwater flow. In addition, much of the water pumped for domestic use would be recharged to groundwater by septic tanks/leach fields and landscape irrigation. Please see Itasca Clarification Memo attached to the Final EIR as Appendix O.

However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies. A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). As described on page 4.8-66 of the DEIR the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. As stated in Section 3.0 of the GMP, the dewatering of the existing mine workings, prior to the commencement of actual mining, is analogous to a largescale pumping test that is a common tool in the field of hydrogeology to assess how drawdowns in the water-bearing zones. Monitoring wells in closer proximity to the mine will generally experience drawdowns before wells farther away. The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Mitigation Measure 4.8-2(a) requires that a projected water-level impact assessment for individual domestic wells shall be performed once dewatering of the underground mine workings commences, based on responses of the measured groundwater levels of the project monitoring wells. The projected groundwater drawdown shall be estimated for each domestic well in the project area. This impact assessment shall be performed by tabulating the variation of the measured water levels from the project monitoring wells over the monitoring period and during the dewatering of the underground mine workings and mining operations. For each domestic well, a projected and seasonally averaged water level shall be estimated based on the domestic well location and the background potentiometric conditions, which will serve as a baseline groundwater level and shall be developed prior to the initiation of dewatering of the underground mine workings. If the water level impact assessment showed a potential impact to wells outside of the E. Bennett area, assuming the 100% safety factor, the applicant would be required to mitigate this impact before it occurs in accordance with Mitigation Measure 4.8-2(b). The mitigation would be for properties which may be potentially impacted as determined in the projected water-level impact assessment. As discussed in the Well Mitigation Plan, if a dewatering impact to an area outside of the E. Bennett

area were projected during operations, pre-emptive action would be taken as necessary to ensure immediate water supply and compensation. The 10% drawdown threshold of significance is extremely conservative and, in most cases, would not lower the water level below the casing of the domestic well. Therefore, well mitigation may not be required after inspection. If reduction of the water column was great enough to reduce the well's yield, a simple adjustment to the pumping system may only be required. For example, by pumping at a lessor rate over a longer duration and if necessary, installing or increasing the size of a pressure or holding tank. In the unlikely case where these measures were not sufficient, appropriate mitigation could be the deepening of a single well, drilling of a new well, or the provision of potable water service to a group of wells. The Well Mitigation Plan has been modified to clarify the actions that would be taken as described above.

## Response to Comment Grp 7-24

The commenter asserts that the groundwater model is incorrect because it does not account for the low-permeability engineered fill to be placed on the Centennial and Brunswick sites. Decreasing the recharge rate over the small area where the engineered fill will be placed would be trivial in comparison to the sensitivity scenarios already performed for the analysis. Please see Response to Comment Grp 7-78.

## Response to Comment Grp 7-25

The commenter asserts that the groundwater model fails to account for the impacts of the proposed new shaft and other existing mine features within a few hundred feet of the surface. However, the service shaft was included in the ground water model. Please see Response to Comment Grp 7-80. All mine workings, including those within a few hundred feet of the surface, were included in the groundwater model (see Figure 2-3 of Appendix K.3).

## Response to Comment Grp 7-26

The commenter suggests that the faults within the project area were not considered in the groundwater model; however, faults were considered in the groundwater model as discussed in Appendix K.3 to the DEIR. Please see Response to Comment Grp 7-64 through Grp 7-94.

## Response to Comment Grp 7-27

The commenter asserts that the DEIR should include monitoring and protections for dewatering due to the faults and irregularities in fractured bedrock. The DEIR includes a groundwater analysis that accounts for the faults and irregularities in the bedrock to determine the extent and severity of impacts to groundwater resources and wells. Further, groundwater monitoring is required for the project, along with other mitigation for dewatering impacts as set forth in Mitigation Measures 4.8-2(a) through 4.8-2(c). See Master Response 14 - Adequacy of Groundwater Model and Master Response 15 - Adequacy of Groundwater Monitoring & Mitigation.

## Response to Comment Grp 7-28

The commenter states that the DEIR acknowledges that more groundwater level data is needed to assess the potential impacts of the proposed project on groundwater levels. The commenter is not correct. The analysis of the DEIR concludes that the proposed mining operations could result in adverse effects to seven domestic water supply wells in the East Bennett area during the life of the mining operation (see page 4.8-66 of the DEIR). A groundwater monitoring plan (GMP) will be implemented by the applicant to assess how the hydrogeologic system responds to mining, whether the measured results are within those modeled under the various scenarios discussed above. This response to dewatering cannot be measured until mine dewatering commences. The

commenter implies that the mitigation is not achievable, enforceable, and capable of reducing the project's impacts. However, the GMP along with the requirement that the applicant provide water to 30 parcels and provide water to any other parcels with wells that are impacted by the project ensures that the mitigation is enforceable by the County, achievable through water replacement requirements, and capable of reducing the project's impacts.

The commenter asserts that groundwater monitoring networks need to be installed prior to dewatering. This is already required at least 12 months in advance per Mitigation Measure 4.8-2(a). This water level monitoring will provide the baseline levels prior to dewatering. The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented.

Please see Response to Comment Grp 21-110.

## Response to Comment Grp 7-29

Please see Master Response 15 and Response to Comment Grp 21-119.

## Response to Comment Grp 7-30

Please see Response to Comment Grp 21-118.

## Response to Comment Grp 7-31

The commenter asserts that the DEIR failed to analyze impacts relating to South Fork Wolf Creek. However, DEIR Chapter 4.4 and Chapter 4.8 analyzed potential project impacts to biological resources and hydrology and water quality affecting South Fork Wolf Creek, respectively. As outlined in Section 4.4.1 (Introduction) and included as Appendix F, eleven different technical studies were prepared documenting existing environmental conditions and analyzing potential biological impacts from the proposed project. This includes a specific biological assessment technical report analyzing treated project water discharge to South Fork Wolf Creek (see Appendix F.10). These technical reports were prepared by biologists with over 30 years of local expertise in the species and environment within the project site. These technical studies were then peer reviewed by the County and their environmental consultants. The peer review of biology reports was conducted by a biological firm with similar local experience that resulted in several rounds of review and revision prior to the County's acceptance of these reports for use in the DEIR. As a result, numerous biological experts with local knowledge have analyzed, and reviewed the characterization and analysis included in these biological technical reports prior to their use and incorporation into the DEIR. In addition, as summarized in Chapter 4.8, and included in appendix H and K, ten different technical reports and peer reviews related to hydrology and water quality were prepared documenting or confirming ground and surface water conditions at the site and potential impacts from the proposed project. Specifically, two technical reports (Appendix K.1 and K.2) analyzed treated water discharge from the project and its potential impact to South Wolf Creek. These technical documents were also peer reviewed by the County and their environmental consultant.

Special status species that may utilize South Wolf Creek were analyzed in Impact 4.4-2 including Foothill Yellow-Legged Frog (FYLF) and Western Pond Turtle. Analysis of the Olive-sided flycatcher, Willow flycatcher, Yellow-breasted chat, and Yellow warbler has been added to Section 4.4 in the Final EIR. No significant impacts to these species was identified. As discussed in Impact

4.4-2, VES method surveys were conducted for FYLF along South Fork Wolf Creek within the project site and portions that flow through public property within Empire Mine State Historic Park. FYLF were not identified during these surveys. Impact 4.4-2 summarizes site and hydrologic conditions in South Wolf Creek within the project site and offsite demonstrating marginal habitat for FYLF. In addition, Impact 4.4-2 addressed potential treated mine water discharge impacts to FYLF and benthic macroinvertebrates and concluded this impact would not be adverse. As explained in Impact 4.4-2, and detailed in Chapter 4.8 and Appendix K.1, the proposed project will discharge a maximum of 5.6 cubic feet per second (cfs) of treated mine water to South Fork Wolf Creek. Base flow in South Fork Wolf Creek may range from 0.17 cfs in the summer to 6.5 cfs in the winter between storm events. Sediment pebble count analysis (see Appendix K.1) indicates that the flow rate at which sediment within the channel may become mobilized ranges from 20 cfs to 90 cfs. With the addition of the maximum proposed discharge of 5.6 cfs and increasing measured baseflows by a 50 percent safety factor, post-project baseflows during nonstorm periods would be expected to range between approximately 5.8 cfs and 15 cfs. These estimates are less than 23 cfs, the threshold for bedload sediment mobility and well below flows that commonly exhibit significant work on the channel (with minimal bed sediment becoming mobilized and minimal or no bank erosion, bed scour, or channel avulsion). The DEIR therefore concludes potential downstream impacts to the stream channel and associated riparian zone along both sides of South Fork Wolf Creek from the additional discharge of 5.6 cfs would be minimal on sensitive biological resources, such as foothill yellow-legged frog, and do not represent a potential significant impact to the stream channel or associated riparian zone within South Fork Wolf Creek. Additionally, peak flows on the South Fork Wolf Creek are expected to be lower than pre-project conditions due to the stormwater detention basin being constructed on the project site as part of the project.

## Response to Comment Grp 7-32

The commenter asserts that the project allows continued mine dewatering up to a rate of 2,500 gpm but did not assess impacts of that higher rate for the operational length of the mine. However, the hydrology and geomorphic analysis specifically considered the discharge of treated mine water at 2,500 gpm throughout operations and not just for initial dewatering. As stated on page 71 of Appendix K.2, the maximum discharge rate permitted will be 2,500 gpm, which will allow flexibility for unexpected seasonal inflows, operational issues, and increased groundwater inflows from the expansion of the mine during operations.

## Response to Comment Grp 7-33

The hydrology and geomorphic analysis considered the seasonality of stream flow as is discussed throughout these reports (see Appendix K.1 & K.2 of the DEIR). Seasonal changes in water temperature have been considered in the DEIR, please see Master Response 32 – Temperature of Mine Water Discharge. Seasonal differences in Specific Conductance and habitat for BMI have no relevance to the analysis of the DEIR as the project discharge will be required to meet fixed thresholds for conductance (see below) and metals content (see Chapter 4.8 of the DEIR) that do not vary based on season and the commenter does not provide any reason why it should be considered in the DEIR.

There are no US EPA water quality criteria for the protection of aquatic life for electrical conductivity, total dissolved solids, and sulphate (See page D-34 of Order R5-2022-0006). However, the secondary MCL for Electrical conductivity of 900 umhos/com is the recommended level for the protection of agricultural supply by the Central Valley Water Board (See page D-34 and D-35 of Order R5-2022-0006). As discussed on page 4-5 of Appendix K.4, electrical

conductivity (EC) is associated with Total Dissolved Solids (TDS). Appendix K.2 listed EC values for the New Brunswick Shaft water as approximately 385 µS/cm. The mobilized divalent ions from the carbonate and sulfide minerals would add to that specific conductance, although it would require significant contributions of Ca, Mg, and SO4 to surpass the NPDES CAG995002 screening level of 900 uS/cm. However, if treatment is deemed necessary for TDS mitigation at some point during mining operations, it is Linkan's opinion that mobile ion exchange water softeners should be deployed as opposed to building additional permanent infrastructure that may not be needed or only needed for relatively short periods. (See DEIR Appendix K.4.) These mobile units are readily available, and various vendors offer the service of replacing them as necessary as the resin becomes spent and in need of regeneration. Additionally, the resins used for these constituents are common throughout the industry for softening water and do not pose a health or environmental risk. Therefore, the proposed water treatment plant is capable of ensuring that conductance of discharged mine water meets water quality goals and the required Notice of Applicability would ensure compliance (Please see Master Response 35 – Discharge to South Fork Wolf Creek).

## Response to Comment Grp 7-34

The impacts to surface vegetation from ground water drawdown was considered in the hydrology analysis. Please see Master Response 33 – Groundwater Dependent Vegetation.

## Response to Comment Grp 7-35

Please see Responses to Comments Grp 32-39 and Grp 32-40 (Wolf Creek Community Alliance).

## Response to Comment Grp 7-36

Please see Master Response 32 – Temperature of Mine Water Discharge and Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 7-37

Please see response to referenced Baseline comment – Response to Comment Grp 21-127 and Master Response 27.

## Response to Comment Grp 7-38

The commenter assumes that if the Centennial site were not available for fill placement, that fill would be immediately hauled to offsite locations which would result in CO2 and NOx emissions exceeding thresholds of significance. However, if the Centennial site were not available, fill placement would take place initially at the Brunswick site rather than being immediately hauled to local and regional construction projects. As stated on page 1-3 of the DEIR, "If the separate DTSC cleanup project is not approved by DTSC and completed within the term of the Idaho-Maryland Mine Project use permit, engineered fill would be placed on the Brunswick site, but not the Centennial site, and the remainder would be hauled to local and regional markets." Moreover, the DEIR already analyzed impacts related to hauling of material to local and regional markets. (Page 1-3 of the DEIR.) GHG emission and NOx emissions would not exceed thresholds in this scenario. Please see response to referenced Baseline comment – Response to Comment Grp 21-122. The applicant has agreed to a condition of approval requiring that if the Centennial Site is not available to accept engineered fill when project operations commence, that the following conditions apply: (a) the engineered fill material will be first placed at the Brunswick Site until that site is at capacity prior to selling waste rock or tailings offsite; or, (b) waste rock or tailings materials sold offsite will be transported in electric trucks.

## Response to Comment Grp 7-39

Please see Master Response 25 - Nevada County Energy Action Plan. As stated on page 4.3-89 of the EIR, The Energy Action Plan (EAP) is not a Qualified GHG Emissions Reduction Plan under CEQA pursuant to the requirements outlined in the CEQA Guidelines, Section 15183.5(D). Therefore, no CEQA document can tier from the County EAP. Nevertheless, the compliance of the project with EAP strategies has been analyzed and the project was found to be consistent with the EAP. (DEIR p. 4.3-90.)

Please see Master Response 27 – Greenhouse Gas Thresholds.

## Response to Comment Grp 7-40

A net zero threshold for GHG emissions is not required for the project. Please see response to referenced Salter comment – Response to Comment Grp 21-130.

## Response to Comment Grp 7-41

Please see response to referenced Salter comment – Response to Comment Grp 21-131 through Grp 21-133.

## Response to Comment Grp 7-42

Please see response to referenced Salter comment – Response to Comment Grp 21-143 and Grp 21-144.

## Response to Comment Grp 7-43

Please see response to referenced CSP comment – Response to Comment Grp 7-188.

## Response to Comment Grp 7-44

Please see response to referenced “mine exhaust moisture” comment – Response to Comment Grp 7-95.

## Response to Comment Grp 7-45

Please see response to referenced “faulting hazard” comment – Response to Comment Grp 7-96. In addition, please see response to referenced CSP comment – Response to Comment Grp 7-183.

## Response to Comment Grp 7-46

The DEIR includes a comprehensive analysis of the potential hazards due to seismic activity in Chapter 4.6, Geology, Soils, and Mineral Resources. Please see Responses to Comments Grp 7-96 and Grp 7-183.

## Response to Comment Grp 7-47

Please see Master Response 4 relating to the Separate Centennial Project.

## Response to Comment Grp 7-48

Please see Master Response 1. The commenter provides no specific reason why they believe health issues and noise impacts are vastly underestimated. These issues have been analyzed in the DEIR.

## Response to Comment Grp 7-49

Mine waste and related run-off is managed by the Waste Discharge Requirements, per CVRWQB requirements. Please see Master Response 8 – Mine Waste Characterization. In addition, please see Response to Comment Grp 7-7 regarding stockpiling concerns.

## Response to Comment Grp 7-50

Please see Responses to Comment 9-5 through 9-7. Compliance with a regulatory permit or other similar process may be identified as mitigation if compliance would result in implementation of measures that would be reasonably expected, based on substantial evidence in the record, to reduce the significant impact to the specified performance standards (CCR Title 14 Section 15126.4).

## Response to Comment Grp 7-51

Asbestos and silica release have been evaluated in the DEIR. Please see Master Responses 21 and 22.

## Response to Comment Grp 7-52

The commenter provides no specific reason why they believe the groundwater model has significant errors, omissions, and is unreliable. These issues have been analyzed in the DEIR. Please see Master Response 14 - Adequacy of Groundwater Model.

## Response to Comment Grp 7-53

The commenter provides no specific reason why they believe well monitoring is inadequate. These issues have been analyzed in the DEIR. Please see Master Response 15 - Adequacy of Groundwater Monitoring Wells.

## Response to Comment Grp 7-54

The commenter claims the DEIR is inadequate under CEQA, but provides no specific reasons in this comment. The commenter's specific comments are addressed in the preceding responses. No further response is required.

## Response to Comment Grp 7-64
The commenter asserts that there is "scant data" relating to the groundwater outflow values reported in the DEIR. However, measured outflows from the drains were completed by EMKO in April 2019 for the preparation of the Groundwater Hydrology and Water Quality Analysis (Appendix K.2 of the EIR) and are presented in Section 3.3.4 of that report. As discussed in the responses below, existing drain outflow is not relevant to the groundwater model, therefore additional flow measurements are not necessary.

## Response to Comment Grp 7-65
There have not been seasonal flow measurements at the drains to determine the seasonal variation. The current flow rate from the drains was not used for the preparation or calibration of the Groundwater Model and therefore additional measurements are not relevant to the analysis.

## Response to Comment Grp 7-66
The commenter asks what the current outflows are at the Wolf Creek drains under the current model. In the calibration of the model during recovery (1956 to 2019), mine voids were simulated with a zone of high K (5,000 ft/day) and high specific yield (effective porosity of 50%) for the area with drifts and raises. The drain nodes for the mine workings were turned off. The drains along Wolf Creek were simulated as drained with surveyed elevated from 2,497 ft to 2,502 ft amsl. The model recovered water level was then compared against measured groundwater levels in domestic wells in the mine area. Please see Itasca Memo attached to the EIR as Appendix K.3. The current flow rate from the drains was not used for the calibration of the Groundwater Model as explained in Response to Comment Grp 7-21. Therefore, a comparison to the measured flow rate is not relevant to the preparation of the model.

## Response to Comment Grp 7-67
Please see Response to Comment Grp 7-68.

## Response to Comment Grp 7-68

The commenter asserts that the groundwater outflow discussed in earlier reports for previously proposed mining projects at the site disclosed different outflow volumes from the mine into Wolf Creek. However, this discrepancy is not relevant to the impact analysis in the DEIR, as the Groundwater Model used in the DEIR did not model the current outflow at the drains. The report mentioned by the commenter is a report titled Idaho-Maryland Mine Technical Assessment prepared by James Askew Associates Inc in May 1991. The reference to 500 – 1200 gpm is the historic mine inflow during operations (when the mine was dewatered) as is made clear in Sections 2.3.1 and 7.2.4 of that report. There appears to have been a mistake in drafting of some sections of this report in 1991 where the historic groundwater inflow into the mine is incorrectly attributed to represent the flow rate from the mine drains. This was clearly a drafting error in the report as can be confirmed by reading the historic report. For example, on page 7 of Appendix C, James Askew Associates estimated 150-200 gpm would be lost from the mine discharges when the mine is dewatered (rather than 500 -1200 gpm). In Table 2 of Appendix C, the report provides the measured flow from the drains taken on March 21st 1991. This table provides the following flow data for the drains: IMD-1 = 50 gpm, ED-1 = 110 gpm, IMD-2 = 30 gpm, Drain = 20 gpm (across the street from Roto-Rooter building). These measurements of drain flow are similar to measurements of flow presented in Appendix K.2 of the DEIR.

## Response to Comment Grp 7-69

The current flow rate from the drains was not used for the calibration of the Groundwater Model and therefore additional measurements would not be relevant to the analysis. Please see Response to Comment Grp 19-21, Grp 19-66 and Grp 19-68.

The goal of the predictions prepared in the groundwater model is to show the location and the magnitude of the estimated drawdowns relative to the baseline (2019 current condition) in order to determine the potential impact of the project to domestic water wells. A water budget/balance is not necessary to complete this goal and therefore not relevant to the analysis of the DEIR. The commenter does not explain how monthly water budgets would be used or how they would alter the conclusion in the DEIR.

## Response to Comment Grp 7-70

The commenter asserts that the analysis of seasonal measurements of the level of water in the mine is flawed and does not support the transmissivity assumptions used in the groundwater model. However, the commenter's assumptions about the analysis are incorrect, as the observations presented in Section 3.3.3.3 of Appendix K.2 of the DEIR are not used as the basis for estimating transmissivity values used in the Groundwater Model. Section 3.3.3.3 of Appendix K.2 of the DEIR discusses the water level in the mine which remains relatively constant at the elevations of the mine drains and is not correlated with rainfall. As the commenter mentions, and is discussed in Section 3.5.2 of the report, the water level in the mine is controlled by the elevation of the mine drains. Domestic wells, discussed in Section 3.3.2.2, show a seasonal fluctuation between wet and dry parts of the year that remains constant over many years. If a domestic well, where ground water levels are higher than the level of water in the mine, were directly connected to the mine workings, the groundwater level in the wells would be controlled by the water level in the mine and a correlation would be observed. As described on page 81 of Appendix K.2, the lack of a seasonal pattern in the mine water levels indicates that the mine workings are not directly connected to the wells by through-going fractures but are instead interconnected by a complex pattern of many fractures present throughout the bedrock.

## Response to Comment Grp 7-71

The commenter asserts that seepage of water could occur in the more permeable zone near the surface. The DEIR's analysis concurs that seepage into the mine shafts in the more permeable region near surface is occurring as discussed in Section 3.5.2 of DEIR Appendix K.2.

## Response to Comment Grp 7-72

As discussed in Section 3.5.2 of the report, the water level in the mine is controlled by the elevation of the mine drains. There are multiple mine drains at different elevations as shown in Table 3-2, with the East Eureka Drain at ~2497 ft msl, the East Eureka shaft at 2501 ft msl, and the Eureka Drain at 2502 ft msl. If the water height in the Brunswick shaft increases the hydraulic head also increases and the additional drains at higher elevations start to discharge water and consequently the resistance to flow decreases. The physical layout of the shafts tunnels and drains therefore ensure that the water level in the shaft is maintained within a few feet throughout the years and seasons. Therefore, the water level in the mine is not expected to be consistently correlated with rainfall. The fluctuations in the water levels identified in this comment for certain years are less than four feet in any given year, in contrast the seasonal fluctuations observed in domestic wells in the project vicinity are typically several tens of feet per year (see discussion in Appendix K.2 of the DEIR and the Response to Comment Grp 7-77, below). The fluctuations observed in the water levels in the shaft are nominal, at best, compared to the magnitude of the fluctuations in the actual groundwater levels and the variations in the amount of rainfall from year to year. The commenter's requests for more granularity of data would serve no purpose because the relationship of the water elevation in the shaft to the drain elevations is well understood.

## Response to Comment Grp 7-73

Revising the graph in Figure 3-7 to 68 inches would not show a direct correlation between precipitation and water level in the shaft. As can be seen in the graph the water levels in the shaft taken by EMKO in 2018 and 2019 only vary by 2 feet. The water level in the mine is controlled by the elevation of the mine drains and not consistently correlated with rainfall. Please see Response to Comment Grp 7-72.

## Response to Comment Grp 7-74

As stated in Appendix K.2, the water level in shafts during this time period were measured by Idaho-Maryland Mining Corporation and presented in a report titled Domestic Well Monitoring Baseline Report (2007). The table of measurements from this report is reproduced below. In March 2005 the water elevation is reported at 2491.8 ft and in July 2005 reported at 2488.2 ft. A few months later in September 2005 the water elevation is reported at 2490.8 ft. Then in December 2005 at an elevation of 2488.4 ft. These differences in water elevation are within a few feet. The water elevation in winter (December 2005) is nearly identical to the water elevation in mid-summer (July 2005). A consistent seasonal correlation is not implied by this data. The water level in the mine is controlled by the elevation of the mine drains and not consistently correlated with rainfall. Please see Response to Comment Grp 19-72.

**Table 4 – New Brunswick and Round Hole Shaft Water Elevations**

| New Brunswick | 2750 Feet Collar Elevation | | | |
|---|---|---|---|---|
| Date | Depth to Water | Units | Water Elevation | Units |
| 3/28/2003 | 268 | Feet | 2482 | Feet |
| 6/13/2003 | 258.38 | Feet | 2491.62 | Feet |
| 9/12/2003 | 258.88 | Feet | 2491.12 | Feet |
| 6/11/2004 | 168.68 | Feet | 2581.32 | Feet |
| 9/17/2004 | 258.46 | Feet | 2491.54 | Feet |
| 12/10/2004 | 257.87 | Feet | 2492.13 | Feet |
| 3/11/2005 | 258.23 | Feet | 2491.77 | Feet |
| 7/18/2005 | 261.84 | Feet | 2488.16 | Feet |
| 9/16/2005 | 259.18 | Feet | 2490.82 | Feet |
| 12/22/2005 | 261.64 | Feet | 2488.36 | Feet |
| 3/16/2006 | 260.76 | Feet | 2489.24 | Feet |
| 6/23/2006 | 263.47 | Feet | 2486.53 | Feet |
| 9/22/2006 | 262.59 | Feet | 2487.41 | Feet |
| | Average Elevation | | 2496.3 | |

| Round Hole | 2665 Feet Collar Elevation | | | |
|---|---|---|---|---|
| Date | Depth to Water | Units | Water Elevation | Units |
| 3/28/2003 | 175 | Feet | 2490 | Feet |
| 6/20/2003 | 174.47 | Feet | 2490.53 | Feet |
| 9/12/2003 | 175.46 | Feet | 2489.54 | Feet |
| 6/11/2004 | 174.68 | Feet | 2490.32 | Feet |
| 9/17/2004 | 174.07 | Feet | 2490.93 | Feet |
| 3/11/2005 | 174.29 | Feet | 2490.71 | Feet |
| 7/18/2005 | 175.16 | Feet | 2489.84 | Feet |
| 9/16/2005 | 175.17 | Feet | 2489.83 | Feet |
| 12/22/2005 | 178.81 | Feet | 2486.19 | Feet |
| 3/16/2006 | 175.51 | Feet | 2489.49 | Feet |
| 6/28/2006 | 176.44 | Feet | 2488.56 | Feet |
| | Average Elevation | | 2489.6 | |

## Response to Comment Grp 7-75

The observations presented in Section 3.3.3.3 of Appendix K.2 of the DEIR are not used as the basis for estimating transmissivity values used in the Groundwater Model. The commenter's statements are based on a misunderstanding of the groundwater model and the data used to create the model.

The volume of water inflow into the mine is correlated with seasonal rainfall as shown by the range of historic inflows into the mine during operations as disclosed in the DEIR. As discussed in Section 3.5.2 of the report, the water level in the mine is controlled by the elevation of the mine drains.

## Response to Comment Grp 7-76

The current flow rate from the drains was not used for the calibration of the Groundwater Model and therefore additional measurements would not be relevant to the analysis, please see Response to Comment Grp 19-21. An estimate of transmissivity versus depth was prepared by EMKO based on well completion reports as discussed in Section 3.3.5 of the Appendix K.2 of the DEIR. The Ground Water Model prepared by Itasca (Appendix K.3 of the DEIR) assigned hydraulic conductivity (K) values derived from reference values and depth as discussed in Section 4.3.1 of that report. After calibration, the assigned K values were found to be within the ranges of EMKO's estimated K values and literature values.

## Response to Comment Grp 7-77

As disclosed in Section 3.3.2.2 of Appendix K.2 of the DEIR, the water levels in the private domestic wells have seasonal fluctuations that may range from 10 feet to 50 feet between wet and dry times of the year but remain relatively consistent from year to year within each individual well. During the monitoring period, several years with below normal rainfall occurred (2001, 2004, and 2007), multiple years with above normal rainfall occurred (1995-1998 and 2006), and several years of near-normal rainfall occurred (1999, 2000, 2002, 2003, 2005). Despite large variations

in annual rainfall from year to year, the seasonal water level cycles in individual wells remain consistent over time and the overall water levels shown on the hydrographs for each well do not fluctuate based on wet or dry climatic cycles.

Based on the lack of changes in the individual well hydrographs between wet and dry climatic cycles, the amount of recharge, as described in Section 3.2, appears to be consistent from year to year and is not affected substantially by drought or wet cycles.

Itasca performed an analysis of the impacts of changing recharge on predicted inflows to the mine and the resulting impacts to drawdowns in shallow groundwater. Changes in recharge would address changes in precipitation. These sensitivity scenarios (Scenarios 4 and 5) are discussed in Section 5.4 of Appendix K.3 of the DEIR. The results are that increasing or decreasing recharge by 50% only changes the predicted inflows to the mine by +/- 3% compared to the base case. The small changes in predicted inflows are due to the low Ks of the deeper geologic units where the mining will occur. Higher recharge reduces the area of drawdown. If the recharge rate in the model domain is decreased by 50%, the extent of the 5-ft drawdown isopleth is larger than in the Base-Case Scenario, as decreased recharge impacts the shallow water-bearing zones more than the deep zone. The 5-ft drawdown isopleth is generally still within the mineral-rights boundary. As shown on Figure 5-9 of Appendix K.3, the simulated 5-foot drawdown contour for Scenario 5 is very similar to the other sensitivity scenarios except for an expansion of the 5-ft drawdown to the south-east towards the greenhorn area by approximately 1500 feet. As further discussed on page 8 of Appendix K.3 of the DEIR, the consistent annual recharge may be due to the limitations of recharge in fractured bedrock, where the annual rainfall amount may be greater than the capacity of the fractures to accept additional flow. In this situation, increases or decreases in the annual rainfall due to climatic cycles do not have appreciable effects on the amount of water that can be recharged because the capacity of the fractures to transmit water in the subsurface is near its maximum. Thus, there may not be a substantial variation in recharge to the water-bearing geologic materials in the project area. Nevertheless, the sensitivity of the model to changes in recharge has been evaluated. The future effects of climate change on groundwater recharge are unknown and CEQA does not require the analysis of speculative impacts. Please see Master Response 16 - Drought and Climate Change. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." As the impact of climate change on recharge is speculative, this impact need not be analyzed in an EIR. However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies. An increase in drawdown caused by the project due to reduced groundwater recharge would be detected in the required well monitoring and well mitigation plans. A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). Ongoing groundwater monitoring would be required, and groundwater-level information shall be obtained from the project groundwater monitoring wells and collected on a quarterly basis and submitted in report form to the Nevada County. Mitigation Measure 4.8-2(b) requires, if based on the GMP, it is determined that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project Applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified.

Consumptive water uses from individual wells are not considered because of the lack of consumptive-use data and the fact that consumptive use is small relative to regional groundwater fluxes. In addition, much of the water pumped for domestic use would be recharged to groundwater by septic tanks/leach fields and landscape irrigation. Please see Itasca Clarification Memo attached to the Final EIR as Appendix O.

## Response to Comment Grp 7-78

The commenter asserts that the DEIR fails to account for potential decrease in groundwater recharge due to the project development. As discussed in the previous response, Sensitivity Scenario 5 decreased recharge by 50% over the entire model area. Decreasing the recharge rate over the small area where the engineered fill will be placed would be trivial in comparison to the sensitivity scenarios already performed for the analysis. However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies. An increase in drawdown caused by the project due to reduced groundwater recharge would be detected in the required well monitoring and well mitigation plans. Please see Response to Comment Grp 7-77.

## Response to Comment Grp 7-79

The commenter asserts that the groundwater model's conclusions are flawed because the assumptions regarding surface area of the underground mine works are not accurate. However, the surface areas of mine workings or drift dimensions were not used to estimate groundwater transmissivity and therefore do not affect the assumptions of transmissivity and the overall hydrological model whatsoever.

As discussed in Section 4.4 of Appendix K.3 of the DEIR, the historical mine workings were simulated using 9,344 drain nodes, and the future mining operation was simulated with 3,888 additional drain nodes.

The reference to typical drift dimensions of 7.5ft x 8.5 ft on page 37 of Appendix K.2 of the DEIR is attributed to Amec Foster Wheeler Americas Limited. (2017). Technical Report on the Idaho-Maryland Project, Grass Valley, California, USA. Vancouver, BC. as indicated in the report.

## Response to Comment Grp 7-80

The commenter asserts that the proposed new service shaft was not included in the groundwater analysis and no cone of depression is included with regard to the new shaft. However, the service shaft was included in the ground water model, and a small cone of depression is clearly shown at the proposed service shaft location on Sheet 12 of DEIR Appendix K.2 (located near the center of the Brunswick Industrial Site).

The proposed service shaft is located approximately 440 ft east of the South Fork Wolf Creek as shown in Figure 3-8 of the DEIR. The service shaft and the excavation to construct it will not be within 100 feet of the creek.

The excavation to install the service shaft is described on page 3-22 of the DEIR. The overburden (i.e., soil and weak rock) would be excavated from the surface and a concrete collar installed from the surface profile to the bedrock. The depth to bedrock is approximately 60 feet. The overburden material would be excavated to allow the shaft and concrete collar to be constructed, and then the overburden would be placed and compacted around the concrete collar to the original ground surface elevation. Any groundwater that infiltrated into the excavation during construction would

be discharged to land (and recharged into the ground) under the requirements of the Construction Stormwater Pollution Prevention Plan (C-SWPPP) required by Mitigation Measure 4.8-1(b) of the DEIR. The excavation would not lead to more groundwater drawdown, or impact near-surface groundwater, because it would be backfilled after construction.

As discussed on page 3.31 of the DEIR, a buried 48-inch culvert crosses the Brunswick Industrial Site. The culvert transports off-site surface drainage from Brunswick Road and a portion of the watershed to the east and south of the Brunswick Industrial Site. South Fork Wolf Creek originates from the outlet of this 48-inch culvert. The primary source that feeds this section of the creek is therefore not associated with groundwater nearby the service shaft area.

## Response to Comment Grp 7-81

The commenter asserts that the near-surface features were not considered in the groundwater model for the DEIR; however, the historic workings of the Idaho-Maryland mine and Union Hill mine were included in the Groundwater Model as shown in Figures 1-1 and 2-3 of Appendix K.3 of the DEIR.

The paragraph the commenter refers to on page 5 of Appendix H.6 clearly refers to the Idaho Shaft. The Idaho Shaft is one of the major shafts of the historic mine and is included in the Groundwater Model.

Itasca Denver considered the location of the Empire mine workings as shown in Figure 2-2 of Appendix K.3 of the DEIR. Please see Itasca Memo attached to the Final EIR as Appendix O.

## Response to Comment Grp 7-82

The commenter states that the groundwater model should assume that all areas within the mineral rights zone would be mined. However, its speculative and unreasonable to assume that economic gold mineralization exists everywhere within the mineral rights at 500 feet below surface. The mining depths analyzed in the groundwater model was based on the applicant's intended mining plan which is focused on the areas where gold mineralization was actually encountered, at depths deeper than 1,000 feet below the surface.

Itasca analyzed the impacts of new underground mining excavations based upon information provided by the applicant as shown on Figures 5-1 of Appendix K.3 and Sheet 15 of Appendix K.2. As shown in these figures, assumed mining areas are based on the projected down-dip extensions to mineralized veins historically mined. Sensitivity Scenario 6 considered the significant expansion of mining in areas with potential for mineralization as shown in Figure 5.10 of Appendix K.3. As shown in Figure 5-12 the major mining expansion studies in Scenario 6 did not result in a significant expansion in the simulated 5-foot drawdown contour versus the base case.

As stated on page 31 of Appendix K.3, it is expected that the actual mining areas will change from the modeled mining areas due to vein geometry and discoveries, which will only be known after extensive underground exploration is completed in the future. Itasca recommends that the groundwater flow model be updated periodically after dewatering commences. Updated modeling would incorporate changes to the long-term mining plan, data from monitoring wells, and measured pumping rates.

However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies. A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). As described on page 4.8-66 of the DEIR the measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. As stated in Section 3.0 of the GMP, the dewatering of the existing mine workings, prior to the commencement of actual mining, is analogous to a largescale pumping test that is a common tool in the field of hydrogeology to assess how drawdowns in the water-bearing zones. Monitoring wells in closer proximity to the mine will generally experience drawdowns before wells farther away. The measurements of water levels in the monitoring wells can be used to verify the groundwater drawdowns as dewatering progresses to provide sufficient time to predict adverse impacts to domestic wells before they occur so that appropriate mitigation measures can be implemented. Mitigation Measure 4.8-2(a) requires that a projected water-level impact assessment for individual domestic wells shall be performed once dewatering of the underground mine workings commences, based on responses of the measured groundwater levels of the project monitoring wells. The projected groundwater drawdown shall be estimated for each domestic well in the project area. This impact assessment shall be performed by tabulating the variation of the measured water levels from the project monitoring wells over the monitoring period and during the dewatering of the underground mine workings and mining operations. For each domestic well, a projected and seasonally averaged water level shall be estimated based on the domestic well location and the background potentiometric conditions, which will serve as a baseline groundwater level and shall be developed prior to the initiation of dewatering of the underground mine workings. If the water level impact assessment showed a potential impact to wells outside of the E. Bennett area, assuming the 100% safety factor, the applicant would be required to mitigate this impact before it occurs in accordance with Mitigation Measure 4.8-2(b). The mitigation would be for properties which may be potentially impacted as determined in the projected water-level impact assessment. As discussed in the Well Mitigation Plan, if a dewatering impact to an area outside of the E. Bennett area were projected during operations, pre-emptive action would be taken as necessary to ensure immediate water supply and compensation. The 10% drawdown threshold of significance is extremely conservative and, in most cases, would not lower the water level below the casing of the domestic well. Therefore, well mitigation may not be required after inspection. If reduction of the water column was great enough to reduce the well's yield, a simple adjustment to the pumping system may only be required. For example, by pumping at a lessor rate over a longer duration and if necessary, installing or increasing the size of a pressure or holding tank. In the unlikely case where these measures were not sufficient, appropriate mitigation could be the deepening of a single well, drilling of a new well, or the provision of potable water service to a group of wells. The Well Mitigation Plan has been modified to clarify the actions that would be taken as described above.

## Response to Comment Grp 7-83

The commenter asserts that the groundwater model should be run for an 80-year period rather than 65 years. The groundwater model was based on the expected mining plan during year one to year 25, and then Sensitivity Scenario 6 considered the significant expansion of mining in areas with potential for mineralization as shown in Figure 5.10 of Appendix K.3 of the DEIR for an additional 40 years of mining. As shown in Figure 5-12, and discussed on page 29 of the report, the 5-ft drawdown contour extent of Scenario 6 at the end of potential additional mining (to Year 65) relative to the 2019 water level expands less than 500 ft from that of the Base-Case Scenario.

The drawdown contour of the Base-Case Scenario is at the end of the original planned future mining (Year 25) relative to the 2019 water level. The comparison of drawdown contours between Scenario 6 and the Base-Case Scenario suggests that the added potential mining (beyond the 65 years modeled) will not lead to large incremental drawdowns as the mining progresses because the mining activities occur in deep, low-K rocks.

As stated in the previous response the groundwater flow model would be updated periodically after dewatering commences and additional groundwater level data is collected to evaluate, dewatering impacts. New groundwater level data and updated modeling would incorporate changes to the long-term mining plan, data from monitoring wells, and measured pumping rates.

Information on the code MINEDW including a list of projects in which MINEDW was used for groundwater modeling is provided in the appendices of Appendix K.3 of the DEIR.

## Response to Comment Grp 7-84

As stated in Section 4.0 of Appendix K.3 of the DEIR, the groundwater flow model that was constructed for this investigation utilizes the numerical code MINEDW, which was developed by Itasca (2012) to solve 3-D groundwater flow problems with an unconfined (or phreatic) surface using the finite-element method. MINEDW is a commercial software that was thoroughly reviewed by Sandia National Laboratories (Corbet et al. 1998). MINEDW has been used successfully at more than 100 mine sites located throughout the world and in diverse hydrogeologic and climatic conditions. The code has been in use for approximately 30 years, and its predictions have been validated by field data collected over many years.

## Response to Comment Grp 7-85

The predicted inflow and water-level drawdown over time is provided in the report (Appendix K.3 of the DEIR).

## Response to Comment Grp 7-86

Initial conditions and data inputs have already been provided throughout the report in DEIR Appendix K.3.

## Response to Comment Grp 7-87

All assumptions and data used for the preparation in the simulation have been provided in DEIR Appendix K.3.

## Response to Comment Grp 7-88

The commenter questions the groundwater model's assumptions regarding transmissivity and anisotropy ratios and consideration of faulting. As stated on page 15 of Appendix K.3 of the DEIR, the assignment of the anisotropy ratio of 10 was based on model calibration. As stated on page 15 of Appendix K.3, based on the model calibration, all of the geologic units were assigned an anisotropy ratio (i.e., a Kx/Kz value) of 10. The description of the model calibration is provided in Sections 4-5 and 4-6 of the report.

Faults in the mine area, 6-3 fault and Morehouse fault were modeled and included in the analysis as discussed in Appendix K.3. The Idaho fault was not modelled but is located at the lithological boundary between the Brunswick Porphyrite Block and the serpentinite unit as discussed on page 4 of the report.

As shown in Table 4-2 of the report the 6-3 and Morehouse faults are assigned hydraulic conductivity (k) significantly lower than (less permeable than) the surrounding strata in the weathered to middle zones for the base case. Therefore, the requested analysis of the commenter has already been completed. As discussed in Section 5.4 of the report, sensitivity Scenario 2 increases the K value of these faults by one order of magnitude and Scenario 3 excludes the faults from the model. The most sensitive scenario is used to estimate impacts to wells as discussed on page 80 of Appendix K.2.

## Response to Comment Grp 7-89

As discussed in the previous response, the requested analysis has already been performed as the base case.

## Response to Comment Grp 7-90

As stated on page 15 of Appendix K.3 of the DEIR the assignment of the anisotropy ratio of 10 was based on model calibration (see Response to Comment Grp 7-88). Therefore, modelling with different anisotropic ratios would not be appropriate.

## Response to Comment Grp 7-91

The three main faults, Morehouse fault, Idaho fault, and 6-3 fault discussed in the Amec Foster Wheeler Americas Limited (2017) Technical Report on the Idaho-Maryland Project have been considered in the model as discussed in Response to Comment Grp 7-88.

Figures 7.8 and 7.9 of that report show additional lessor faults which are part of the Idaho Fault Zone as discussed in Section 7.3.1 of that report. Therefore, these faults have already been considered as part of the Idaho fault.

Figure 7-10 of that report shows several minor faults (22, 20, 11, 20C) which are coincident with veins of the Brunswick veins which are already mined and are shown not to extend towards the surface in the figure. As discussed on page 13 of Appendix K.3 of the DEIR, the minimum horizontal length of an element is about 20 to 25 ft. Therefore, the modeling of these minor faults would serve no purpose because most of this area is already modelled as mining voids. Please see Itasca Clarification Memo attached to the Final EIR as Appendix O.

## Response to Comment Grp 7-92

Scenario 3 excludes the faults from the model as discussed in Response to Comment Grp 7-88. Therefore, the removal of all of the “impermeable fault wall” has already been considered in the analysis.

## Response to Comment Grp 7-93

Groundwater levels are discussed in Section of 3.3.2.2 of Appendix K.2 of the DEIR. There are no references to measurable drop offs in groundwater surface topography.

## Response to Comment Grp 7-94

Please see Response to Comment Grp 7-64 through Grp 7-94.

## Response to Comment Grp 7-95

The commenter expresses concern regarding mine exhaust moisture affecting air traffic at the nearby Nevada County Airport. The Nevada County Airport Land Use Compatibility Plan (ALCP) provides information on policies for compatibility planning in the vicinity of the Nevada County

airport. The northern portion of the Brunswick site and New Brunswick shaft is in Zone D – Traffic Pattern Zone of the Nevada County Airport (See Map 2A of ALCP). The Federal Aviation Regulations (FAR) Part 77 Surfaces at the location of the shaft is at an elevation of 3,307 feet or higher (See Map 2B of ALCP). Objects which exceed the FAR 77 height limits constitute airspace obstructions. The top of the proposed New Brunswick shaft headframe is at an elevation of approximately 2,921 ft above mean sea level (MSL), which equates to at least 386 feet below the FAR surface.

At 200,000 cubic feet per minute (CFM), ventilation exhaust velocity at the exit of the headframe opening (approximately 14 feet by 30 feet) would be approximately 476 feet per minute (5.4 miles per hour [mph]). The velocity would quickly diminish but even at maximum velocity is less than the average wind speed at the Nevada County Airport (approximately 6 mph).

The ventilation system for the mine downcasts fresh air into the mine at the Service shaft. As the air descends, it is compressed, and this auto compression increases the air temperature. As the air travels through the mine, it gains additional heat from the natural temperature of the rock. The moisture carrying capacity of air increases with temperature and water used in the mine is absorbed by the air as it travels through the mine workings. When mine air is exhausted back to the surface at the Brunswick shaft, the auto-compression of the air reverses and the air expands and cools. The moisture carrying capacity of the air decreases and excess water released (water vapor and precipitation) as it upcasts through the shaft. The result is that exhausted air is at or near saturation point when it reaches the surface. The natural rock temperature influences the air temperature and therefore the exhausting air temperature would be fairly constant through the seasons. If the ambient air temperature is low, the mixing of the air could result in water vapor as the mine air is further cooled. This water vapor would be quickly dispersed.

The mixing of air at two different state points results in air at an intermediate state point. The new state point is a function of the flow rates of the original masses of air. Considering a column of air from the top of the headframe to the FAR (386 feet above top of headframe) at the average wind speed of 6 miles per hour (528 feet per minute), the 200,000 CFM mine exhaust would be mixed with 4,484,000 CFM of ambient air and only comprise 4.3% of the mixed air. On a calm day (1.1 mph or 0.5 m/s windspeed), the mine air would only compose 19% of the mixed air. The actual mixing would be much greater than this simple example as the column of air is dispersed and exposed to increasing mass flow of ambient air.

Due to the relatively low velocity of airflow and large amount of mixing expected between the headframe and the airport, there is no potential impact to aircraft in the traffic pattern zone of the Nevada County Airport due to the project. In certain conditions (i.e., calm and very cold days), water vapor could be visible immediately above the headframe. Complex modeling and viewpoint renderings of water vapor would not change the conclusion of the DEIR and therefore is not required for the project.

https://wind.willyweather.com/ca/nevada-county/grass-valley.html

https://www.nctc.ca.gov/documents/NCALUC/NCALUCP%20Final%209-21-11%20-%20Chapter%202%20-%20Policies.pdf

## Response to Comment Grp 7-96

The commenter asserts that the DEIR should have evaluated the project's potential to activate local faults and induce seismic activity due to the removal of rock and placement of fill. However, the magnitude of the mine rock excavation and placement is far smaller than the magnitude of the mass of bedrock underlying the site. The magnitude of the energy released during mining excavations by rock removal and rock placement is much smaller than the magnitude of energy activation required to trigger the release of a local pre-Holocene fault. No analysis was performed or is necessary, as there is no potential for inducement of seismic activity on these faults from the proposed mining activity. Please see the NV5 Memo attached as Appendix P to the Final EIR.

## Response to Comment Grp 7-97

Please see Response to Comment Grp 7-96.

## Response to Comment Grp 7-98

Please see Response to Comment Grp 7-96.

## Response to Comment Grp 7-99

Extensive geotechnical analysis was performed for the project as evidenced by the analysis in Chapter 4.6, Geology, Soils, and Mineral Resources, of the DEIR. Please also see Response to Comment Grp 7-96.

## Response to Comment Grp 7-100

Please see Response to Comment Grp 7-96. No impact to integrity of near surface historical and proposed mine works would occur from the placement of engineered fill on surface. The magnitude of the mine rock placement is far smaller than the magnitude of the mass of bedrock underlying the site where these tunnels are located.

## Response to Comment Grp 7-101

The location of proposed buildings within the area of the 6-3 fault shown on the drawing provided by the commenter has already been extensively analyzed in the DEIR. Please see Section 4.6 and Appendix H.2 of the DEIR.

## Response to Comment Grp 7-102

The magnitude of the energy released during mining excavations by rock removal and rock placement is much smaller than the magnitude of energy activation required to trigger the release of a local pre-Holocene fault. Please see Response to Comment Grp 7-96. Given that the larger faults do not present geotechnical concerns, lesser faults in the mine area also do not present concerns of significance. Seismicity and faulting have been thoroughly analyzed in the DEIR. Please see Chapter 4.6 of the DEIR.

## Response to Comment Grp 7-103

The commenter notes that a sampling plan for asbestos under the relevant Asbestos ATCMs has not yet be approved by the NSAQMD. However, the sampling plan does not need to be approved until rock production commences. The Asbestos ATCM for Construction, Grading, Quarrying and Surface Mine Operations and Asbestos ATCM for Surfacing is applicable to the project because a portion of the area to be disturbed is located in a geographic ultramafic rock unit. A Geological Evaluation would be required if an exemption from the ATCM's was requested. Such an exemption is not being requested.

In accordance with the ATCM for Surfacing, and the required use of ARB 435 Test Method, prior to conducting any sampling, the sampling plan shall be submitted to the Northern Sierra Air Quality Management District (NSAQMD) for approval. This is not required until the mine produces rock from the underground mine.

## Response to Comment Grp 7-104

The requirements of ARB Method 435 in relation to the ATCM for Surfacing is discussed in the ASUR Plan (Appendix E.2 of the DEIR). The California Air Resources Board announced on May 18, 2017 the release of the Implementation Guidance Document for Test Method 435 Field Sampling and Laboratory Practices. This guidance document is intended to be used in conjunction with the regulation, Test Method 435, to assist laboratories, consultants, local air pollution control districts, and other asbestos stakeholders in the application and performance of M435. This non-regulatory guidance document consists of clarifications and recommendations. Notably, the guidance document contains recommendations, not requirements of ARB Method 435.

## Response to Comment Grp 7-105

The ASUR Plan was authored by the applicant based on applicable regulations and sound geologic principles. The ASUR Plan is a management plan and discusses how rock will be managed (including sampling and testing) in the future during operations; however, the ASUR Plan is not a state regulatory requirement and therefore is not subject to certain licensing requirements. As such, the current licensing of the applicant's management, directors, and consultants is not relevant. However, it should also be noted that the California Air Resources Board's ATCMs that pertain to naturally occurring asbestos are the overarching regulations with which the project is required to comply, and the ASUR Plan was developed to be consistent with the ATCMs; however, the ASUR Plan does not supersede requirements contained within the ATCMs. As such, any licensing requirements in state law relating to implementation of the ATCMs will still apply to the project.

## Response to Comment Grp 7-106

Asbestos by Polarized Light Microscopy (PLM) cannot be directly compared to Transmission Electron Microscopy (TEM) or Phase Contrast Microscopy (PCM) results. The OEHHA Guidelines provide a conversion of TEM structures to PCM equivalent fibers and from PCM fibers to PCM weight percent.

## Response to Comment Grp 7-107

The commenter provides a description of PCM asbestos testing methods, advantages and disadvantages. As stated on page 18 of the ASUR plan, underground mining operations are obligated to comply with MSHA (Mine Safety and Health Administration) Federal Regulations. Potential asbestos fiber concentrations shall be determined by phase contrast microscopy (PCM) for compliance with MSHA regulations for worker exposure to asbestos.

As stated on page 7 of the ASUR plan, TEM is the method recommended by OEHHA. However, TEM measurements cannot be directly related to the cancer potency factors because the studies upon which OEHHA's risk assessment was based used PCM analysis. Thus, the TEM measurements must be converted to PCM-equivalent units. The public health risk assessment prepared for the project has been developed in accordance with OEHHA Guidelines.

## Response to Comment Grp 7-108

The commenter provides a description of PLM asbestos testing methods, advantages and disadvantages. PLM testing is required to comply with the Asbestos ATCM for Surfacing.

## Response to Comment Grp 7-109

The commenter inquires how the method for bulk sampling was modified for rock cores. The modifications and sample preparation used by the laboratory are detailed on page 89, the cover sheet for Asbestos TEM Laboratories of Appendix E.2 of the DEIR. Sample preparation followed a standard CARB 435 prep method. The entire sample was dried at 135-150 C and then crushed to ~3/8" gravel size. If the submitted sample was >~1 quart, the sample may have been split using a 1/2" riffle splitter following ASTM Method C-702-98 to reduce the sample volume for pulverization. The remaining aliquot, or entire original sample, was then pulverized in a Bico Braun disc pulverizer calibrated to produce a nominal 200 mesh final product.

## Response to Comment Grp 7-110

Asbestos by Polarized Light Microscopy (PLM) cannot be directly compared to Transmission Electron Microscopy (TEM). PLM testing is required to comply with the requirements of the Asbestos ATCM for Surfacing. TEM testing is OEHHA's preferred analytical approach for outdoor asbestos samples because of its ability to detect small fibers (greater than or equal to 0.0002 microns in diameter) and to distinguish between asbestos fibers and non-asbestos fibers. As such, TEM testing is OEHHA's recommended approach to conduct a health risk assessment.

## Response to Comment Grp 7-111

Please see Master Response 23 - Adequacy of Asbestos Sampling.

## Response to Comment Grp 7-112

The commenter asserts that some samples are mislabelled in Asbestos Sample Memo June 2020 Appendix A. This report is not included in the DEIR but is referenced in the ASUR plan (Appendix E.2 of the DEIR). The photo in Appendix A is mislabeled as Y962880 instead of Y962980. This is a typo in the report and has no effect on the analysis of the DEIR. The commenter asserts that asbestos sampling was "extremely limited" and stopped drilling when asbestos was detected. Please see Master Response 23 - Adequacy of Asbestos Sampling.

## Response to Comment Grp 7-113

The commenter questions why samples with different TEM weight percentages can have equivalent PCM fiber counts, and questions why duplicate samples may show different results. For the purposes of the Air Toxics Hot Spot Program, asbestos should be converted using the relationship of 1 PCM Fiber = 320 TEM structures (OEHHA Appendix C). TEM weight percent is not used and has no relevance to a health risk assessment. TEM weight percent will vary depending on the size and mass of each structure detected. Duplicate samples are taken from the same location of drill core but are not identical samples. Therefore, it is expected that there will be variations in naturally occurring asbestos fibers between samples. The commenter's conclusions regarding asbestos content are incorrect because the commenter mistakenly correlates TEM weight with PCB fiber count, which are not directly correlated.

Grouping by lithology is important as mining is planned and completed in the distinct geological units present in the mine. As the commenter notes, serpentine is a lithology of concern due to the presence of chrysotile asbestos.

## Response to Comment Grp 7-114

The commenter asks why the report was revised and questions the implication of not having blind blanks or blind duplicates, along with the implication of noted grid opening damage and possible contamination. The laboratory provided their final work product which is included in the appendix of the ASUR Plan. The laboratory report NO.375516 is marked as rev.1 because the results from sample Y962992 was not included in the first version of this report. This incomplete "original" version of the laboratory report is redundant and its inclusion in the ASUR plan is not required. Grid openings damage is noted by the laboratory and is part of their internal processes. As a certified laboratory it is up to the lab to determine whether a damaged grid unacceptably impacts the accuracy of their reporting results and repeat testing if deemed necessary. Where only a single structure of asbestos is detected the laboratory notes "possible contamination". This does not affect the analysis of the DEIR other than adding additional conservatism with the assumption of asbestos that does not exist. Duplicates and blanks were not re-inserted as the 40 samples previously submitted (and analyzed by PLM) were reanalyzed using the TEM method. Blanks and duplicates were inserted into the original group of samples. However, future sampling during operations under the ASUR Plan will require a Quality Assurance Quality Control program which would require blanks and duplicate samples.

## Response to Comment Grp 7-115

The commenter questions the implication of the possibility of amphibole asbestos in the rock versus chrysotile asbestos. The commenter asserts that there may be different health risks associated with different types of asbestos; however, OEHHA guidelines do not attribute different cancer risk for amphiboles and chrysotile asbestos fibers. OEHHA is the lead state agency for the assessment of health risks posed by environmental contaminants in California, and the health risk assessment is required to be based on OEHHA guidelines.

## Response to Comment Grp 7-116

The commenter asserts that the presence of certain elements in asbestos fibers may affect the toxicity of those fibers. However, OEHHA guidelines do not attribute different cancer risk based on metal content or presence of other elements. The OEHHA guidelines provide the mandatory methodology for use in health risk assessments.

## Response to Comment Grp 7-117

The commenter asserts that the samples submitted for laboratory analysis of metal toxic air contaminants were "expired" because they were submitted in early 2019, but could have been drilled as early as 2017. However, rock material does not "expire" after even a few years. The analyses related to metals were conducted on native geologic material that have been present in the environment for many millions of years. The purpose of the testing was to assess the potential for actions related to the proposed project to mobilize naturally-occurring metals within the minerals in the rock. The time between collection of the rock sample and the lab analysis, and the temperature at which the rock samples were stored or transported, has no effect on the presence or mobility of the naturally occurring metals within the rock itself. As such, the hold times for the rock samples do not affect the validity of the results or the validity of the DEIR's analysis.

## Response to Comment Grp 7-118

The commenter questions whether the ASUR plan's proposed method of obtaining samples complies with CARB Method 435, as the ASUR plan requires samples to be taken at the transfer point in between the skip and the silo. The commenter implies that the ASUR's method is not proper because it does not draw directly form a storage pile, conveyor belt, or aggregate covered

surface. The ASUR Plan complies with CARB Method 435, Section 5.2 of which states that "The grab samples shall be taken from the product staking belt or if this is not possible then at the first transfer point before the stockpile." Page 13 of the ASUR Plan states that "Samples will be taken from the transfer point between the skip and silo and may be taken either manually or with an automated sampler." As such, the ASUR plan complies with CARB Method 435. Moreover, the method apparently suggested by the commenter of placing all the material into a large stockpile could actually lead to greater air quality impacts. The project proposes no outdoor stockpiles, and by keeping the material in silos reduces impacts associated with any dust created by stockpiles.

## Response to Comment Grp 7-119

The employee tasked with taking the sample would take the sample at the transfer point. The internal structures of the headframe, including platforms etc., are not shown on Figure 2 of the ASUR plan and are not required for the purpose of the illustration.

## Response to Comment Grp 7-120

The commenter asserts that taking a sample of barren rock prior to its placement in the silo may be appropriate, but that such sampling is not appropriate for tailings because that sampling point is not the point closest to the end of processing, as the commenter asserts is required by Carb Method 435. However, the commenter has truncated its cited reference to CARB Method 435 requirements. The full text on page ii of the Implementation Guidance Document ARB Test Method 435 document states: "Choose to sample aggregates on conveyor belts closest to the final product rather than piles if at all possible."

Notably, the above sentence is a recommendation, not a requirement of ARB Method 435. The ASUR plan does not propose to sample from piles, so this recommendation is not directly applicable to the tailings. The sampling point chosen allows for testing to be completed before the material is transported for use in surfacing and is the closest sampling point that is practical to the end product for the tailings.

## Response to Comment Grp 7-121

The commenter asks at what intervals the 3 samples will be taken per 1,000 tons. Sampling is at random intervals and not at set timing. As required by ARB Method 435, the method of randomly choosing the sampling locations and intervals is left up to sampling personnel but must follow the procedure specified in the sampling plan (which would be approved by NSAQMD).

Two methods of asbestos testing are required under the ASUR Plan. PLM testing is required to comply with the Asbestos ATCM for Surfacing and trucks may not transport material without a receipt based on the PLM results. Any materials with detectable asbestos would not be allowed to be used for surfacing.

The commenter also asks whether barren rock and mineralized rock would be analyzed separately. Barren rock and mineralized rock would be analyzed separately to allow the issuance of the required receipt. Barren and mineralized rock are placed in different bins of the silo.

As discussed on page 4.3-61 of the DEIR, the average asbestos content of the total mined material is of primary concern given that asbestos does not have established acute noncancer effects. The purpose of TEM testing in the ASUR Plan is not to control the fate of the rock and tailings after it reaches surface (that is the purpose of the PLM testing described above). Rather,

the TEM testing is done to verify that mine planning is effectively minimizing the potential for public exposure to airborne asbestos from the project.

## Response to Comment Grp 7-122

The commenter questions the purpose of the different testing methods used as part of the ASUR plan. As described below, the ASUR plan utilizes TEM and PLM testing of material, but uses each method for different purposes, as appropriate.

The ASUR includes both an Engineered Fill Placement Plan and Asbestos Inventory. The Engineered Fill Placement (EFP) Plan (Section 8.5 of the ASUR Plan) will include schedules and planned material placement locations and haul roads. The EFP Plan will be designed to ensure that Asbestos Containing Material is not used for Surfacing. The EFP Plan will designate areas which are suitable for the placement of Asbestos Containing Material and maintain an estimate of the capacity of these areas. Whether material is suitable for Surfacing is determined by PLM testing in accordance with the Asbestos ATCM for Surfacing.

The Asbestos Inventory (Section 8.3 of the ASUR Plan) is based on asbestos content, using TEM testing, which is to verify that mine planning is effectively minimizing the potential for public exposure to airborne asbestos from the project.

## Response to Comment Grp 7-123

As discussed on page 4.3-61 of the DEIR, the average asbestos content of the total mined material is of primary concern for health risk impacts given that asbestos does not have established acute noncancer effects. The purpose of TEM testing in the ASUR Plan is not to control the fate of the rock and tailings after it reaches surface. The TEM testing is done to verify that mine planning is effectively minimizing the potential for public exposure to airborne asbestos from the project.

A new weighted average will be calculated upon the receipt of analytical results from TEM testing as described in the ASUR Plan. No material is planned to be “stored” or “maintained”. Mining will continue as normal during the two week turn-around time for TEM samples. The asbestos content mined material is managed through the measures of the ASUR plan which included exploration sampling, mine planning, and testing of materials on surface to monitor and ensure the effectiveness of these measures.

The commenter provides a theoretical example of a sample which has no detectable asbestos by PLM (and therefore suitable for use in Surfacing) but has detectable asbestos by TEM testing. A sample which has detectable asbestos does not “fail” as the commenter asserts. Rather the measures of the ASUR Plan fail if the rolling three-month weighted average of materials brought to surface exceeds 0.01% asbestos in equivalent PCM units. The ASUR Plan describes measures which prevent such a failure from occurring and also actions that would be taken if such a failure did occur. The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials. Samples would not be re-tested as individual samples do not “fail” as discussed above.

## Response to Comment Grp 7-124

The commenter asks how the 500 tons of material designated for cemented paste fill will be selected, and how it will be culled from the inventory. The amount of cemented paste fill poured underground is estimated to average 500 tons per day, but will vary based on operational

considerations and availability of mine voids underground. The selection of which materials are used for backfill is determined by technical and management personnel of the operation. The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials.

## Response to Comment Grp 7-125

No large-scale temporary storage facilities are proposed for the project. The project includes temporary storage of materials at the Brunswick Shaft, inside the process plant, and at the Brunswick and Centennial sites where material would be dropped by trucks and later graded and compacted during weekday daylight hours. Toxic air contaminant fractions within particulate matter have been estimated based on these material processes and were already incorporated into the Health Risk Assessment.

## Response to Comment Grp 7-126

The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials.

## Response to Comment Grp 7-127

The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials. Accordingly, the rock truck loading building is not designed to hold inventory of rock. Rather the inventory of rock is held in the silo until loaded into trucks.

## Response to Comment Grp 7-128

No trucking is allowed during nighttime hours (8 hours of the day). During this overnight period the sand tailings produced from mineral processing are stockpiled inside the process plant building. This material must be loaded into trucks by a front-end loader outside of the process plant building the following day.

## Response to Comment Grp 7-129

Sand tailings will be stored inside the process plant building overnight, but will be loaded into trucks by a front-end loader outside of that building. The loader loads its bucket from a stockpile located inside the building and loads the waiting truck outside of the building. The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials. Accordingly, there would be no changes to the loading procedures due to inventory issues that would affect the noise or air quality impacts. Noise from this equipment has been analyzed in the DEIR. Additionally, asbestos health risk is associated with long-term exposure and correlates to the average asbestos content of all mined materials. Given that asbestos is not an acute toxin, “decontamination” of the equipment is not necessary nor required for the project. Rather, changes in the mine plan would be developed to prevent and respond to any higher than anticipated asbestos content as disclosed by TEM testing. The Health Risk assessment assumes average asbestos content of all dust at 0.01% weight percent asbestos in PCM equivalent units. The potential for equipment and storage areas to generate dust is included in the analysis which has determined the risk to the public from this dust to be less than significant after mitigation.

Engineered fill (barren rock and sand tailings) are kept separate in the process plant and in trucks delivering the materials to their destination. Once they are used for engineered fill at the destinations they would be blended as necessary for geotechnical criteria and operational

planning. As discussed on page 14 of Appendix H.1 of the DEIR, laboratory testing of selective ratio of blended materials would be conducted to verify geotechnical parameters. Nuclear density gauges or procedural test methods would be used to verify compaction reached required densities as appropriate.

## Response to Comment Grp 7-130

Shotcreting of wall for asbestos mitigation is contemplated in Section 6.1 of the ASUR Plan when planned tunneling in Barren rock is projected to result in the Asbestos Inventory 3-month rolling average to exceed 0.01% by mass of equivalent PCM units. This situation is not expected based on the percentage of asbestos encountered in samples obtained from the project site; however, in such an unlikely situation, the entire tunnel project would be considered to contain significant asbestos. The greenhouse gas from the manufacturing of cement is not attributable to the project for analysis of GHG emissions in the DEIR analysis. The use of shotcrete is expected to be minor and any transport of this material is accounted for in the freight trucks already included in the air quality analysis. Shotcrete application is a wet process and generates minimal dust. Hexavalent chromium could be present in cement but would not be mobile once shotcrete is cured, similar to any concrete product. The use of shotcrete would be trivial in comparison to the mass of cement used in cemented paste backfill.

## Response to Comment Grp 7-131

The commenter asks whether shotcrete will be used in all tunnels. Shotcrete is used as ground support in certain situations where rock bolts and screens are not sufficient. In construction of most new underground works shotcrete is not expected to be required based on the solid character of the rock encountered during drilling.

## Response to Comment Grp 7-132

The commenter asks whether and how asbestos will be removed from mine water and how much volume of water may be contaminated with asbestos. Note that the word “sediments” is missing from the sentence in the ASUR Plan that is cited by commenter. This is an editing error in the document.

The corrected sentence should read:

> “Water generated from drilling and dust suppression during tunneling in Asbestos Containing Material shall be collected in sumps or tanks and sediments shall not be used for Surfacing.”

Contrary to commenter’s implication, there is no separate water process for asbestos containing water, as all water pumped from the mine will follow the same treatment path, which involves removal of solids. Sumps or tanks used in the underground mine are designed to remove the majority of solids from the water. The water would then be pumped to main underground sumps located on various levels, then to the surface water treatment pond. Solids would be removed from water at all these stages. Under the requirements of Order R5-2022-006 the final discharge must have less than 10 ppm total suspended solids (Average monthly) and 7MFL (million fibers per liter) asbestos in water. Accordingly, any water discharged from the project will have been treated at multiple stages and will be required to comply with RWQCB standards for numerous constituents, as well as asbestos content.

## Response to Comment Grp 7-133

The commenter asks whether the MERV 16 filters will be limited to serpentinite mining only, what type of filters are used in the main ventilation system, and what is the quantity of asbestos in the total mined quantity of serpentinite. No filtration is proposed in the main ventilation system. Air filtration is contemplated in Section 6.1 of the ASUR Plan when planned tunnelling in Barren rock is projected to result in the Asbestos Inventory 3-month rolling average to exceed 0.01% by mass of equivalent PCM units. Asbestos emissions are controlled by utilizing dust collection (air filtration).

The filtration measures in Section 6.1 of the ASUR Plan ensure that asbestos emissions that flow into the mine ventilation system are not increased beyond the baseline scenario (with all mined material averaging 0.01% PCM equivalent asbestos content). Therefore, the assumed ratio of serpentinite in barren rock is not relevant to the health risk assessment.

For example, serpentinite sample Y962992 (Appendix C of the ASUR Plan) contains the highest content of asbestos from exploration sampling with 7.3 TEM structures per nanogram or 0.069% PCM equivalent weight percent. The dust generated from each activity would be reduced by 95% by air filtration before entering the main ventilation system and exhausting to surface. The dust emission factor (EF) for the activity remains constant.

Serpentinite sample Y62992 with filtration
Asbestos dust per ton mined = 0.069% x EF x 5% = 0.0035% x EF

Maximum ASUR asbestos content without filtration
Asbestos dust per ton mined = 0.01% x EF = 0.0100% x EF

Page 300 of the Air Quality Technical Report refers to existing mine fill at the Brunswick site which will be disturbed during site construction and assumes a conservative serpentinite content for the purpose of the health assessment due to limited testing in this area. The Health Risk Assessment assumes the maximum asbestos content possible under the ASUR Plan for mining materials derived from proposed underground mining.

The commenter also asked how the mine fill can be 14% serpentinite if only 1% of mined material is serpentinite. Contrary to the commenter's statement, engineered fill was not assumed to have 14.3% serpentinite; rather, the existing mine fill at the Brunswick site was assumed to have 14.3% serpentinite. As discussed on page 300 of the Air Quality Technical Report, existing mine fill at the Brunswick site will be disturbed during site construction and the report assumes a conservative serpentinite content for the purpose of the Health Risk Assessment due to limited testing in this area. Based on the overall serpentinite content found in the rock underlying the site, and the testing on the existing fill material, the 14.3% assumption likely overstates the serpentinite in the existing fill. For material that will be mined at the site as part of the project and brought to the surface, the Health Risk Assessment assumes the maximum asbestos content possible under the ASUR Plan for mining materials derived from proposed underground mining.

## Response to Comment Grp 7-134

Based on cited language from the ASUR Plan, the commenter asks why the mine operator would remove barren rock surrounding mineralization if it is not going to mine the gold mineralization. Gold mineralization is treated differently than barren rock in Section 6.0 of the ASUR Plan (Mine Planning) because the gold mineralization must be crushed, hoisted to surface, and processed.

These activities could generate significant dust which could be harmful if the materials contained significant asbestos. As such, if identified gold mineralization contains sufficiently high asbestos content such that its mining would cause the 3-month rolling asbestos inventory average to exceed 0.01% asbestos by mass of PCM equivalent units, that gold mineralization would need to be avoided. Conversely, engineering controls for tunneling in barren rock can be more easily implemented and the material could remain underground. As described on page 3-19 of the DEIR, new underground tunnels and raises would be created as necessary to access gold-quartz veins or provide the necessary underground infrastructure to transport rock and provide ventilation and escape routes. As such, the mine operator may need to mine through barren rock to reach other target areas, even if certain gold mineralization is avoided.

## Response to Comment Grp 7-135

The commenter requests that the mine operator be required to maintain records of asbestos content in mined material indefinitely. The ASUR Plan is intended to reflect the requirements of the ATCM's which are attached to the ASUR plan.

Section (e)(5)(A) of the Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations requires the maintenance of certain records (including air monitoring) for 7 years following the completion of construction or grading operations. Section (f)(5)(A) of the ATCM requires the owner/operator of a surface mining or quarrying operation to maintain certain records (including air monitoring) for at least 7 years.

Section (e) of the Asbestos ACTM for Surfacing requires receipts (verifying the asbestos content) to be retained for a minimum period of seven years from the date of supply or use of the material. As such, there is no legal requirement to keep records beyond 7 years, and there is no environmental impact associated with not maintaining these records indefinitely.

## Response to Comment Grp 7-136

The ASUR plan is part of the project description and will be required by the County pursuant to a condition of approval. As such, the ASUR Plan will be binding on any successors in interest to the mine. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring. Components of the ASUR Plan will become part of the approved ADMP and other components will be used as company policy and procedures to assist with compliance with the ADMP. Accordingly, the ADMP is the tool used by the NSAQMD for enforcement, rather than the ASUR plan. Nonetheless, the ASUR plan is binding on the applicant, can be enforced by the County, and to the extent that provisions in the ASUR plan are incorporated into the ADMP, those provisions would be enforceable by the NSAQMD.

## Response to Comment Grp 7-137

The commenter asserts that the 3-month rolling inventory will cause increased fugitive dust emissions; however, the commenter misunderstands the rolling inventory and seems to believe that it is a physical stockpile of 3-months of mined material. The rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials. The project site is not designed to hold 3-months of mined material in inventory and will not do so.

The commenter also asks whether all material can be properly assumed to contain only 0.01% asbestos for purposes of calculating air emissions. The assumption that all mined rock will average 0.01% is appropriate and the Health Risk Assessment' analysis of asbestos-related health risk is based on conservative assumptions. Please see Master Response 22 – Conservatism used for Asbestos Assumptions.

The commenter also states that qualification of asbestos content is not possible until after testing by TEM occurs, which may not be known for two weeks, resulting in unknown impacts to the public. This is not an accurate statement; as discussed in Section 6.0 of the ASUR Plan asbestos content is determined by TEM during the exploration and pre-mining phase before mining is commenced. The TEM sampling conducted on materials (barren rock and sand tailings) at surface is done to verify that mine exploration and planning is successfully minimizing the content of asbestos in mined materials brought to surface. Therefore, the TEM testing is done on samples prior to actual mining to improve mine planning and avoid impacts.

As stated on page 4.3-42 of the DEIR, the NSAQMD's cancer and noncancer thresholds to assess health risk significance for CEQA are consistent with what are used for the AB 2588 risk assessment procedures. The threshold of significance for health risk is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concluded that the health risk to the most sensitive receptor will be below this threshold.

Nevertheless, the DEIR concludes that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the EIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring. Components of the ASUR Plan will become part of the approved ADMP and other components will be used as company policy and procedures to assist with compliance with the ADMP.

Notably, compliance with the CARB ATCMs for naturally occurring asbestos, including development of an ADMP, is the standard approach within CEQA documents to address health concerns associated with exposure to asbestos from unpaved surfaces, construction and grading operations and quarries where asbestos is found or likely to be found in order to ensure potential health risk impacts to the public would be minimized to a less than significant impact. Multiple other projects in the NSAQMD jurisdiction, as well as throughout the state, have relied upon compliance with these naturally occurring asbestos ATCMs in order to control any potential asbestos emissions to the extent possible. As described in Mitigation Measure 4.3-2 of the DEIR, the proposed project shall also comply with all applicable criteria in the CARB ATCMs for naturally occurring asbestos.

## Response to Comment Grp 7-138

The commenter notes that the HRA prepared for the project uses a 30-year exposure timeframe, and asks what health impacts will occur after that 30-year period. As stated on page 26 of the Health Risk Assessment (Appendix E.1 of the DEIR), OEHHA describes cancer risk evaluations for 9-, 30-, and 70-year exposure durations in the 2015 OEHHA Guidelines and identifies that the 9- and 30-year durations correspond to the average and high-end of residency time

recommended by the EPA, with the 30-year exposure duration recommended for use as the basis for estimating cancer risk at the maximally exposed individual resident in all HRAs. OEHHA recommends that a 30-year exposure duration be used as the basis for estimating cancer risk at the maximum exposed individual resident (MEIR) in the Hot Spots Program. This exposure duration represents the time of residency for 90 to 95% of Californians at a single location and should provide adequate public health protection against individual risk. (Section 8.1 OEHHA 2015 Air Toxics Hot Spots Program Manual). As standard practice, the duration of exposure is based on 30-year sensitive receptor residency rather than the life of a project.

Further, additional conservatism is layered into OEHHA's recommendations that were incorporated into the HRA prepared for the project, including the assumption that exposure at all sensitive residential receptors would begin in the 3rd trimester of gestation, which accounts for the higher sensitivity of infants and children by applying age-specific daily breathing rates and age-sensitivity factors (ASFs), and that the baby grow through childhood and adulthood at the same home for the next 30 years. This scenario is unlikely to happen, yet it evaluates and reflects conservative, health-protective methodologies to assess health impacts to adults, as well as infants, children, and other sensitive subpopulations.

## Response to Comment Grp 7-139

The commenter questions the use of meteorological data in the HRA. Please see Master Response 17 - Meteorological Data Used in HRA.

## Response to Comment Grp 7-140

The attainment status of Nevada County is discussed on page 4.3-9 and shown in Table 4.3-3 of the DEIR. Western Nevada county is in attainment for PM2.5 and non-attainment for PM10. Ambient Air Quality Standards are determined by the US and California EPA and not the World Health Organization.

As discussed on page 4.3-41 of the DEIR, the NSAQMD established thresholds of significance for CEQA purposes to achieve and maintain the National and California Ambient Air Quality Standards (AAQS). Because an AAQS is based on maximum pollutant levels in outdoor air that would not harm the public's health, and air district thresholds pertain to attainment of the AAQS, a project that complies with the thresholds established by a local air district, such as the NSAQMD, would not result in adverse effects to human health related to criteria pollutant emissions. The NSAQMD thresholds of significance for PM10 and PM2.5 do not consider baseline measurements, so the commenter's request for baseline measurements is not relevant to the significance analysis in the DEIR.

Regarding the health risk assessment, the threshold of significance for exposure to toxic air contaminants is based on an incremental increase in cancer and non-cancer risk associated with a project. As such, the baseline concentration does not factor into this impact determination.

## Response to Comment Grp 7-141

The County acknowledges the comment and notes it expresses the opinions of the commenter, and does not raise an issue related to the adequacy of any specific section or analysis of the DEIR. The County will include the comment as part of the Final EIR for review and consideration by the decision-makers prior to a final decision on the project. No further response is required or necessary.

## Response to Comment Grp 7-142

The commenter questions the 30-year exposure duration assumption versus the 80-year project life. Please see Response to Comment Grp 7-138 above.

## Response to Comment Grp 7-143

Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

## Response to Comment Grp 7-144

The commenter asks about air quality health impacts to the Durham School Bus Depot. As discussed in Section 2.1 of the Health Risk Assessment, the cancer risk accounts for the higher sensitivity of infants and children by applying age-specific daily breathing rates and age-sensitivity factors (ASFs). Accordingly, the HRA evaluates and reflects conservative, health-protective methodologies to assess health impacts to adults, as well as infants, children, and other sensitive subpopulations.

As stated on page 27 of the Health Risk Assessment (Appendix E.1 of the DEIR), the maximally exposed individual residence (MEIR) would be the nearest existing residence to the north of the Brunswick Industrial Site. Emissions would be dispersed as distance increases from the emission source. Given that the Health Risk Assessment presents the health risk levels at the maximally exposed individual, all other receptors in the vicinity of the project, including the Durham Bus Depot, would have less exposure and consequently less potential health risk than the MEIR.

## Response to Comment Grp 7-145

The commenter requests that the demographics of the community, including age and specific illness rates, be considered in the health risk analysis.

Health risk assessments do not account for County-specific illness rates. However, as discussed in Section 2.1 of the Health Risk Assessment for the project, implementing the OEHHA Guidance, as was done for the project, reflects conservative, health-protective methodologies to assess health impacts to adults, as well as infants, children, and other sensitive subpopulations. For example, the reference exposure levels (RELs) used in the evaluation of non-cancer risk are designed to protect the most sensitive individuals in the population, including infants and children, by selecting appropriate toxicological data and including margins of safety. Accordingly, the evaluation methods are assumed to protect children and other sensitive subpopulations (groups of more highly susceptible individuals) from adverse health effects in the event of exposure. A similar approach was taken for cancer risk, which accounts for the higher sensitivity of infants and children by applying age-specific daily breathing rates and age-sensitivity factors (ASFs), as well as conservative exposure period, fraction of time at home, and cancer potency factors as recommended by OEHHA.

Sensitive receptors, including the facilities mentioned by the commenter, are at a further distance than receptors around the sites and would have less exposure and consequently less potential health risk than the MEIR. Please see Response to Comment Grp 7-144.

## Response to Comment Grp 7-146

The commenter asserts that there is an error in the AERMOD dispersion model, which would indicate the model was run at the wrong elevation. The Base Elevation for STCK8, STCK9, STCK10 shown in Table 2 are in feet. The units shown as meters is an error (typo) in the table. This can be verified in the model output files on page 395 of the document where these stacks are shown at elevations of 837.71, 838.72, and 759.39 meters. As such, the AERMOD dispersion model was run at the correct elevations.

## Response to Comment Grp 7-147

No fuel monitoring or other provisions in regard to the backup generator are proposed or required to be analyzed in the DEIR. As stated on page 58 of Appendix E.1, the Stationary Engine ATCM allows owners and operators of emergency standby engines to use those engines to provide electrical power when a facility experiences the loss of normal electrical service that is beyond the reasonable control of the facility. Electrical service loss resulting from Public Safety Power Shutoff events is beyond the reasonable control of back-up engine owners and operators, and therefore, appropriately permitted emergency standby engines may be operated to provide electrical power during such an event pursuant to the Stationary Engine ATCM. Mitigation for emissions from generator use during power outages is not required because such use is speculative, and it is uncertain if or when such use would occur. Emissions from routine testing of these generators has been included in the emissions of the project.

The commenter asks if there will be penalties if the Teir4F engines are not used exclusively due to “commercial availability” status. Tier 4F generators are commercially available, and therefore will be required to be used for the project. As stated on Page 4.3-49 of the EIR, a representative Cummins model QSK60-G17 generator with a Tier 4F engine was used for emission factors.

## Response to Comment Grp 7-148

The commenter expresses concern regarding silica exposure, and asserts that the Health Risk Assessment underestimates silica content in the rock that will be mined as part of the project. The assumed crystalline silica content and modeling of respirable silica in the Health Risk Assessment prepared for the project is conservative and overestimates the relevant exposure in any situation, as described in Master Response 21 – Conservatism of Silica Assumptions. Given that the Health Risk Assessment uses the most conservative assumptions regarding silica content and exposure, sampling of materials for crystalline silica content is not required.

## Response to Comment Grp 7-149

The commenter questions why mine fill was analyzed at 14.3% serpentinite, when the DEIR assumed that only 1% of the mined material will be serpentinite. Contrary to the commenter’s statement, engineered fill was not assumed to have 14.3% serpentinite; rather, the existing mine fill at the Brunswick site was assumed to have 14.3% serpentinite. As discussed on page 300 of the Air Quality Technical Report, existing mine fill at the Brunswick site will be disturbed during site construction and the report assumes a conservative serpentinite content for the purpose of the Health Risk Assessment due to limited testing in this area. Based on the overall serpentinite content found in the rock underlying the site, and the testing on the existing fill material, the 14.3% assumption likely overstates the serpentinite in the existing fill. For material that will be mined at the site as part of the project and brought to the surface, the Health Risk Assessment assumes the maximum asbestos content possible under the ASUR Plan for mining materials derived from proposed underground mining.

## Response to Comment Grp 7-150

The commenter seems to imply that the rolling inventory is a physical inventory; however, the rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials.

The commenter asserts that the detection limit of PCM equivalent units is 0.01%. However, the detection limit for TEM testing is one structure located within the number of grids scanned. Depending on how many grids are scanned the detection limit would range from approximately 0.0003% to 0.0011% PCM Weight equivalent.

Two methods of asbestos testing are required under the ASUR Plan. PLM testing is required to comply with the Asbestos ATCM. TEM testing is done to verify that mine planning is effectively minimizing the potential for public exposure to airborne asbestos from the project. Please see Response to Comment Grp 7-121.

Drilling was stopped when the exploration geologist determined there was little potential for discovery of gold mineralization and not when asbestos was detected. Asbestos sampling is not done at the same time as drilling and cannot be detected visually at the low levels present without sophisticated microscopy.

Samples from various lithologies at the Idaho-Maryland Mine Project were selected for asbestos testing. Sampling was based on lithologies where mining could take place and not on percentages of drill holes completed during exploration. Please see Responses to Comments 7-111 and 7-112. The location of exploration samples tested for asbestos are shown on sheets 1-3 of the ASUR Plan, sample name, drill hole, downhole depths, sample interval, rock type, and test results are provided in the appendix of the ASUR Plan (Appendix E.2 of the DEIR).

Prior to underground gold mining, intensive planning efforts will be required to meet state and federal regulations and achieve safety, environmental, and economic goals. Underground mine planning includes exploratory drilling, geologic mapping, material logging, and testing. These same processes also ensure future mining operations avoid and manage rock types that may contain naturally occurring asbestos. Please see Section 6.0 of the ASUR Plan (Appendix E.2 of the DEIR).

The commenter states that twenty percent of the samples tested had asbestos levels greater than 0.01% PCM equivalents. However, this ratio has no relevance as the sampling results for asbestos content grouped by rock lithology and the quantities of each lithology mined are what will determine the potential quantity of asbestos exposure from dust generated by mining activities.

The Health Risk Assessment is based on conservative assumptions. Please see Master Response 22 – Conservatism used for Asbestos Assumptions.

Nevertheless, the DEIR concludes that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements

as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

The commenter asserts that the asbestos emissions should not be assumed to be only 0.01% because the applicant cannot control the amount of asbestos in the actual mined material. The commenter is incorrect. As discussed in the ASUR plan the applicant can control the amount of asbestos in actual mined material through exploration, sampling, and mine planning. This sampling is completed before mining of this material and any problematic materials would either not be mined or mined using measures discussed in the ASUR Plan. The ASUR Plan provides specific measures to ensure average asbestos content does not exceed 0.01% PCM equivalent.

## Response to Comment Grp 7-151

The commenter asks how much asbestos will be in the remaining 5% of asbestos fibers after use of MERV filters for situations where serpentinite would be mined. The amount of asbestos released during serpentinite mining would be the same as during mining of non-serpentinite mining through the use of measures outlined in the ASUR plan. The filtration measures in Section 6.1 of the ASUR Plan ensure that asbestos emissions into the mine ventilation system are not increased beyond the baseline scenario (with all mined material averaging 0.01% PCM equivalent asbestos content). Please see Response to Comment Grp 7-133.

## Response to Comment Grp 7-152

The commenter implies that there will be asbestos emissions associated with stockpiling of the rolling inventory, and that these emissions were not analyzed. However, the rolling inventory in the Asbestos Inventory (Section 8.3 of the ASUR Plan) is a digital accounting of asbestos sample results. It does not refer to a physical inventory of mined materials.

The commenter states that the DEIR underestimates the level of asbestos exposure that could be caused by the project. However, the Health Risk Assessment is based on conservative assumptions that likely overestimate asbestos exposure. Please see Master Response 22 – Conservatism used for Asbestos Assumptions.

As stated on page 4.3-42 of the DEIR, use of the NSAQMD's cancer and noncancer thresholds to assess health risk significance for CEQA is consistent with AB 2588 risk assessment procedures. The threshold of significance for health risk is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concludes that the health risk to the most sensitive receptor will be below this threshold.

Nevertheless, the DEIR concludes that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring. Notably, compliance with the CARB ATCMs for naturally occurring asbestos, including development of an ADMP, is the standard approach within CEQA documents to address health concerns associated with exposure to asbestos from unpaved surfaces, construction and grading operations and quarries where asbestos is found or likely to be found in order to ensure potential health risk impacts to the public would be minimized to a less than

significant impact. Multiple other projects in the NSAQMD jurisdiction, as well as throughout the state, have relied upon compliance with these naturally occurring asbestos ATCMs in order to control any potential asbestos emissions to the extent possible. As described in Mitigation Measure 4.3-2 of the DEIR, the proposed project shall also comply with all applicable criteria in the CARB ATCMs for naturally occurring asbestos.

## Response to Comment Grp 7-153

The commenter asserts that the samples submitted for laboratory analysis of metal toxic air contaminants were "expired" because they submitted in early 2019, but could have been drilled as early as 2017. However, rock material does not "expire" after even a few years. The analyses related to metals were conducted on native geologic material that have been present in the environment for literally many millions of years. The purpose of the testing was to assess the potential for actions related to the proposed project to mobilize naturally-occurring metals within the minerals in the rock. The time between collection of the rock sample and the lab analysis, and the temperature at which the rock samples were stored or transported, has no effect on the presence or mobility of the naturally occurring metals within the rock itself. As such, the hold times for the rock samples do not affect the validity of the results or the validity of the DEIR's analysis. Metal content in dust generated by all activities of the project were evaluated in the Health Risk Assessment. Please see also Master Response 20 – Conservatism used for Metals Assumptions.

## Response to Comment Grp 7-154

The comment generally asserts that the health risk assessment is not valid. The commenter's specific comments are addressed in the preceding responses to comments. The County acknowledges the comment and notes it expresses the opinions of the commenter. The County will include the comment as part of the Final EIR for review and consideration by the decision-makers prior to a final decision on the project. No further response is required or necessary.

## Response to Comment Grp 7-155

The commenter describes the drilling program used by Rise to explore the geology beneath the project site. However, the sampling pattern described by the commenter is not accurate. Page 96 of Appendix K.2 states:

> Rise completed 19 drill exploration drill core holes, totaling 67,500 linear feet, from 2017-2019. Exploration drilling was designed to test a variety of mineralization throughput the deposit in areas where mining is expected to occur. Drill core was logged by company geologists in Grass Valley. The core was sawed in half in zones of interest and sent to ALS Laboratories in Reno, Nevada to be assayed.

The drill logs are not necessary for the analysis conducted in Appendix K.2.

## Response to Comment Grp 7-156

The commenter asked whether the sample material submitted for laboratory testing was 2mm material or 6mm material. As stated on page 98 of Appendix K.2 the material was -2mm. During crushing not all material is less than 2 mm as all crushing procedures specify a percent passing 2 mm. Therefore, some portion of the material would be larger than 2 mm. The metallurgical lab noted the material "appeared to be approximately 6 mm in size". They did not state that they measured the particle size.

Sample locations and depth intervals of the 76 mineralized samples used for the metallurgical composite sample are shown on sheets 5, 6, and 7 of Appendix K.2 (noted in Section 4.4.2 of the report).

## Response to Comment Grp 7-157

The commenter provides a description of the selection process for rock samples that were selected to be representative of the barren rock surrounding the mineralized zones and then tested in a laboratory. The commenter implies that the amount of rock tested was of an insufficient volume compared to the total amount of cores collected. As discussed in Section 2.3 of Appendix K.2, an extensive network of underground workings would be constructed throughout the life of the mine to access the gold ore. These underground workings would be constructed within nonmineralized "barren" rock. The barren rock would be used as engineered fill after it is removed from the mine. The barren rock samples used for the geochemical evaluation presented in Section 4.4 of Appendix K.2 were collected to obtain data regarding the general geochemical character of the different geologic formations that would be encountered during mining. The samples were collected by a California-licensed professional geologist with experience in mining to be representative of the individual rock types that make up the barren rock (meta-andesite, altered meta-andesite, diabase, and serpentinite). Each rock type is composed of a relatively uniform lithologic material that formed from a common source. Thus, the general geochemistry of each barren rock type does not vary substantially because it all has a common source and has not been mineralized.

The overall purpose of the barren rock sampling and laboratory analysis was to identify the general characteristics of that specific material type. Given that the objective was to understand the general character of the barren rock, the number of samples or the length of the samples compared to the total linear feet of core drilled for mineral exploration has no relevance. As the samples were selected by a California licensed geologist to be representative of the mineral types expected in the barren rock, the results of the barren rock testing provide reliable and representative results for consideration in the DEIR and for assessment of the potential effects of the use of that material for engineered fill.

Furthermore, prior to mining, the applicant will need to obtain several approvals from the Central Valley Regional Water Quality Control Board (RWQCB), which will require further testing of the rock at the project site. As described in the April 4, 2022 comment letter from the RWQCB, additional laboratory studies will be required to characterize the waste materials as part of a Report of Waste Discharge. The RWQCB cannot issue permits for the placement of engineered fill unless the testing that is part of the Report of Waste Discharge clearly demonstrates that use of the barren rock for engineered fill will not violate water quality standards or conflict with the Water Quality Control Plan. The barren rock testing that was conducted in support of the project application and used in the DEIR provides evidence of the potential water quality effects that might occur due to the use barren rock as engineered fill, while the RWQCB permits, which are a requirement of the project because mining cannot occur until such permits are issued, ensure that water quality standards will be met. Please see Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 7-158

The commenter implies that the amount of core samples submitted for metals analysis is insufficient because samples were drawn from 5 of the 19 cores that were drilled as part of

exploration. Note that the table cited by the commenter, Table 4-9, is located on pages 104 and 105 of Appendix K.2 and not pages 101-102 as stated by the commenter.

As stated on page 98 of Appendix K.2, in addition to the barren rock samples, Rise provided 48 crushed core samples for trace element test work. The 48 samples were unused portions of samples crushed to 2 mm in size (referred to as assay rejects). This material provides additional information on the variability of trace metals that may be present in the rock that would be produced from tunneling in barren rock in different lithologies. All sample locations are shown on Sheets 5, 6, and 7 of Appendix K.2.

The purpose of this sampling is to provide information on materials that may be present in various rock types that would be produced from tunneling, so that the DEIR can properly analyze any impacts from those materials. The areas where tunneling is anticipated to take place are shown on Sheet 15 of Appendix K.2. The purpose of the sampling is not to sample every drill hole and the full lengths of each drill holes (which may be drilled thousands of feet before reaching an exploration target). Rather, samples were taken that are representative of where mining is actually expected to take place, and the types of rock present in those zones, not the thousands of feet of rock that was drilled just to reach the target area. Therefore, the number of samples or the length of the samples compared to the total linear feet of core drilled for mineral exploration has no relevance to whether the samples are representative of the barren rock. The 48 samples were portions of the samples (referred to as assay rejects) remaining from exploration conducted by the applicant and therefore the details on sample weights and assay procedures used to generate the rejects are not included in Appendix K.2. The samples were selected by a professional California-licensed geologist to be of adequate quantity and quality sufficient to represent the barren rock.

## Response to Comment Grp 7-159

As noted by Itasca in the Cemented Paste Backfill study: Samples were analyzed using a strong-acid digestion (EPA 1996) conducted by ACZ. This method is not intended to be a total digestion; however, it is a very strong acid digestion that will dissolve almost all elements that could potentially become environmentally available (E PA. 1996. Method 3050B acid digestion of sediments, sludges, and soils. In Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, SW-846. Environmental Protection Agency, December.)

ACZ laboratories received 47 pulverized samples, (the Barren Rock Crushed Core Samples) which were split from materials previously assayed at ALS Labs. The reference to 48 samples in the Hydrology Technical Report is an error. The 47 pulps from various barren rock lithologies were run for metals content only using ICP-MS. This material provides information on the variability of trace metals that may be present in the rock that would be produced from tunneling in barren rock in different lithologies.

The 6 barren rock samples submitted to ACZ for metals, DI-Wet and acid potential were crushed and pulverized in accordance with EPA method EPA-600/2-78-054 3.1.3 as noted in the ACZ analytical reports contained in the appendix of the Hydrology Technical Report. The samples were analyzed for Total Metals, dissolved metals using California Waste Extraction Testing (WET), and acid potential (ABA) at ACZ.

It is unclear what the commenter means in the statement "Any conclusions comparing metals content, leachate capacity, ABA, etc. between pulp results and barren rock results is moot since the sample preparation (pulverization) is identical."

The crushed core samples were not subject to WET or ABA testwork and no comparisons were made to the barren rock sample results (which were subjected to these tests).

The crushed core samples and barren rock samples were analyzed for total metals using the same method and at the same laboratory.

## Response to Comment Grp 7-160

The commenter questions how the composite sample was prepared and analyzed months before the individual samples were submitted to ACZ. The commenter refers to the composite sample which was used by McClelland Labs to prepare tailings samples F1-F4. As stated on page 98 of Appendix K.2, the composite sample was prepared from 76 samples of -2mm material remaining from assaying (for gold) during exploration. This exploration took place before the barren rock samples were taken to support the analysis presented in Appendix K.2, which explains why the composite sample was prepared before the individual samples.

As stated on page 98 of Appendix K.2, the applicant's geologist selected mineralized samples for metallurgical testwork by reviewing drill logs and maps. A composite sample was prepared from 76 samples of the -2mm material remaining from assaying. A portion of the material from each sample was weighed to represent the interval length and merged to make the metallurgical sample. Sufficient material was available for most samples, except for five samples where no material was available from the assay lab. The 76 samples were unused sample material (referred to as assay rejects) remaining from exploration conducted by the applicant and therefore chain of custody reports are not included in Appendix K.2.

## Response to Comment Grp 7-161

As discussed in Section 4.4.2 of the Hydrology Technical Report (Appendix K.2):

> Rise selected mineralized samples for metallurgical testwork by reviewing drill logs and maps. Samples were selected to be representative of materials expected to be encountered during future mining. Factors considered in selection were gold grades, minimum mining widths, mineralization style, and locations throughout the potential mining areas. Sample locations and depth intervals are shown on Sheets 5, 6, and 7.
>
> A composite sample was prepared from 76 samples of the -2mm material remaining from assaying. A portion of the material from each sample was weighed to represent the interval length and merged to make the metallurgical sample. Sufficient material was available for most samples, except for five samples where no material was available from the assay lab. The 76 samples created a composite metallurgical sample of approximately 46 kilograms (kg) (about 100 pounds).
>
> The 46 kg metallurgical sample was shipped (in a bucket) in July 2019 to McClelland Laboratories in Reno, Nevada for testwork.

The environmental testwork on tailings samples F1-F4 were completed as discussed in 4.4.2 of Appendix K.2. As stated in Section 4.4.1, a California-licensed Professional Geologist from Benchmark Resources collected six drill core samples in Grass Valley on October 29, 2019 from

barren rock intervals. These were the barren rock samples used for the geochemical characterization discussed in this section of the report.

## Response to Comment Grp 7-162

The cores were drilled for mineral exploration purposes such that the number of cores drilled and the length of a certain rock type in each core has no bearing on the amount of barren rock or tailings that may be produced from the mine. The cores were also drilled through thousands of feet of rock that will not be subject to any mining, in order to reach the target zone. Testing of the full length of these cores would misrepresent the type of rock likely to be encountered during mining. The laboratory testing was conducted to identify the general geochemical parameters of each individual rock type or formation. Please see Responses to Comments Grp 7-157 and Grp 7-158.

## Response to Comment Grp 7-163

The commenter generally asserts that not enough samples were analyzed for metals content, and states that only one sample was analyzed from the Brunswick area. See Responses to Comments Grp 7-157 and Grp 7-158 regarding the adequacy of the sampling volume. As shown on Sheets 5-7 of the Hydrology Technical Report (Appendix K.2 of the DEIR), the Brunswick mine is hosted in meta-andesite. Numerous meta-andesite samples were submitted for laboratory testing.

Further mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and obtain approved Waste Discharge Requirements (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). Please see Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 7-164

The commenter asserts that there are issues with the chains of custody for rock samples, and that the samples were drawn from too few of the cores. Chain of Custody forms are presented within the laboratory reports that are part of the appendices to the Appendix K.2 report. These include the submission of the barren rock and tailings samples to ACZ labs which were used for the WET testing that is relevant to the analysis. Some of the exploration testing was not used as part of the evaluations in the Appendix K.2 report and was conducted by the applicant during mineral exploration. As such, sample collection, lab results, and Chain of Custody forms related to that work was not addressed in Appendix K.2.

The selection of samples was done in order to be representative of the rock in which mining will take place, not representative of the full length of each core. Please see Responses to Comments Grp 7-157 and Grp 7-158. The applicant's exploration work was conducted under the supervision of qualified geologist, using a quality control program, and analytical work completed at a professional laboratory, as noted in the disclosure of explorations results published by the applicant. (see below)

Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)).

During this process, a sampling plan that addresses representative sampling of the mining waste would be submitted to the CVRQCB prior to sampling and the CVRQCB would to be notified when the samples are to be collected so that they may observe the process. Collection of field samples and subsequent testing of the expected mining waste would be based on clearly defined objectives identified in a sampling plan prepared by professional(s) registered to practice in California in the field of engineering or geological sciences.

## Response to Comment Grp 7-165

The lithology between these samples is meta-andesite as shown on Sheet 7 of Appendix K.2. The serpentinite begins near the location of sample S-1 and is interpreted to be several thousand feet wide in that region as shown on Sheet 7.

## Response to Comment Grp 7-166

These samples are taken at the contact of the meta-andesite and serpentinite unit as shown on Sheet 7 of Appendix K.2. Downhole or “below” theses samples is serpentinite as is shown on Sheet 7.

## Response to Comment Grp 7-167

The page 510 referenced in the comment seems to be incorrect. The page discussed in the comment seems to be on page 667 of the Hydrology Technical Report pdf. (page 17/21 ACZ Analytical Report project number L57125.

ACZ Laboratories holds certification from the State of Nevada for acid-base accounting methods. Nevada is currently the only state agency offering this certification. https://acz.com/index.php/geochemistry/ The lack of California certification for these methods, cited by the commenter, is not relevant as California does not offer certifications for these methods.

## Response to Comment Grp 7-168

The assumed crystalline silica content and modelling of respirable silica is conservative and overestimates the relevant exposure in any situation. Therefore, sampling of materials for crystalline silica content is not required. Please see Master Response 21 – Conservatism of Silica Assumptions.

## Response to Comment Grp 7-169

The commenter questioned why drilling ceased when serpentinite was encountered. Drilling was stopped when the exploration geologist determined there was little potential for discovery of gold mineralization. Serpentinite is a poor host rock for gold mineralization and holes which encounter it are not continued in this lithology. Mining activity will not be focused in the serpentinite areas, and will attempt to avoid those areas, as there is little or no gold there. Asbestos sampling is not done at the same time as drilling and cannot be detected visually at the low levels present without sophisticated microscopy. Please see Responses to Comments Grp 7-157 and Grp 7-158 regarding volume of sampling and representation of rock types.

The commenter implies that more than 1% serpentinite will be mined because quartz veins run along contact points with serpentinite. Gold mineralization at the contact of meta-andesite and serpentinite are typically hosted in ankerite. Ankeritized serpentinite has negligible asbestos content due to the alteration of minerals that occurs during mineralization (See ASUR Plan - Appendix E.2). Maps showing lithological units and exploration drilling is provided in Sheets 4-7 in Appendix K.2.

The commenter questions why mine fill was analyzed at 14.3% serpentinite, when the DEIR assumed that only 1% of the mined material will be serpentinite. Contrary to the commenter's statement, engineered fill was not assumed to have 14.3% serpentinite; rather, the existing mine fill at the Brunswick site was assumed to have 14.3% serpentinite. Page 300 of the Air Quality Technical Report refers to existing mine fill at the Brunswick site which will be disturbed during site construction and assumes a conservative serpentinite content for the purpose of the health assessment due to limited testing in this area. The Hydrology Technical Report refers to estimated mining materials derived from proposed underground mining.

The Health Risk Assessment is based on conservative assumptions. Please see Master Response 22 – Conservatism used for Asbestos Assumptions.

## Response to Comment Grp 7-170

The commenter asks how the ratios of the different types of rock to be mined can be known. The ratios of different barren rock types to be mined is shown in Table 4-5 of Appendix K.2 and is based on mine models developed by the applicant as shown on Sheet 15 of Appendix K.2. As stated in Section 4.4.1 of Appendix K.2, most of the underground work that would occur as part of the project would be tunneling to access the ore deposit and to provide access routes to move material and provide ventilation. These workings would be almost exclusively within barren meta-andesite rock. Cross-cuts into the mineralized veins would produce some altered meta-andesite, as well as diabase and serpentinite in some of the Idaho vein areas. The ASUR Plan, Mitigation Measure 4.3-2, and conservatism of assumptions in the Health Risk Assessment would ensure the protection of the public from heavy metals, silica, and asbestos should the ratio of rock mined vary from the assumed ratios estimated by the applicant.

Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP.

Assumptions used in the health risk assessment for respirable silica are already very conservative. Further sampling would reduce the impact from silica. Please see Master Response 21 – Conservatism of Silica Assumptions.

Metal content of dust emissions are considered in the health risk assessment based on sampling and material ratios presented in Section 4.4 of Appendix K.2. The Health Risk Assessment used conservative assumptions of metal content in fugitive dust. Please see Master Response 20 – Conservatism of Metals Assumptions.

## Response to Comment Grp 7-171

The commenter asked why more testing was not done in the Brunswick area. As shown on Sheets 5-7 of the Hydrology Technical Report (Appendix K.2 of the DEIR), the Brunswick mine is hosted in meta-andesite. Numerous meta-andesite samples were submitted for laboratory testing. Please see Responses to Comments Grp 7-157 and Grp 7-158 regarding volume and representation of samples from cores.

## Response to Comment Grp 7-172

The commenter asked how the data from the sampling can be extrapolated to 2,585 acres of mineral rights that could potentially be mined. Economic gold mineralization does not exist everywhere within the 2,585 acres of mineral rights, so the geology of much of the 2,585-acre area is not relevant. As shown on Sheet 15 of Appendix K.2, assumed mining areas are based on the projected down-dip extensions to mineralized veins that were historically mined.

The barren and mineralized rock samples used for the geochemical evaluation presented in Section 4.4 of Appendix K.2 were collected to obtain data regarding the general geochemical character of the different geologic formations that would be encountered during mining.

As described in Chapter 3 (page 3-19) of the DEIR, underground exploration would take place after mine dewatering is complete and throughout the life of the mine. Exploration would be done primarily with diamond core drilling throughout the mine area. Exploration would produce core samples that would be brought to the surface for analysis to determine future mining areas. Therefore, numerous additional samples would be taken throughout the mine life, and the mine operator can adjust mine planning depending on the information obtained from additional samples.

## Response to Comment Grp 7-173

This is an introductory comment. The commenter's specific comments are addressed in the responses to comments below.

## Response to Comment Grp 7-174

This is an introductory comment. The commenter's specific comments are addressed in the responses to comments below.

## Response to Comment Grp 7-175

The commenter opines that the project does not have sufficient information to meet the standards set forth for Canadian National Instrument 43-101. Canadian National Instrument 43-101 and regulatory definitions of Mineral Resources and Mineral Reserves are public disclosure regulations designed for the protection of investors investing in Canadian markets and are not relevant to the CEQA process for approval of a mine permit. As described in Chapter 3 of the DEIR Underground exploration would take place after mine dewatering is complete and throughout the life of the mine and would be done primarily with diamond core drilling throughout the mine area.

## Response to Comment Grp 7-176

The commenter states that the sample testing method used for the project is not consistent with standards for Australian mine projects. However, Australian mining standards are not applicable in California, and the commenter fails to note the additional waste rock characterization that is required in California as part of the Report of Waste Discharge under California law and as mitigation by the DEIR. The level of testing completed thus far is appropriate for analysis of impacts under CEQA, and additional testing will be required for approval of WDRs. Please see Master Response 8 – Mine Waste Characterization. Mining waste regulations applicable in California are described on pages 4.8-28 through -30 of the DEIR.

Section 4.4 of Appendix K.2 of the DEIR provides geochemical testwork conducted on tailings and barren rock samples from the project site. Testwork included Acid Based Accounting (ABA), Total Metals, and California Waste Extraction Testing (WET). The Waste Extraction Test (WET) should be used to determine the amount of extractable substance in waste rock (CCR Title 22 Division 4.5, Chapter 11, Article 5, Appendix II). The overall purpose of the barren rock and tailings sampling and laboratory analysis was to identify the general characteristics of that specific material type. Given that the objective was to understand the general character, the number of samples or the length of the samples compared to the total linear feet of core drilled for mineral exploration has no relevance. As such, the results of the barren rock testing provide reliable and representative results for consideration in the DEIR and for assessment of the potential effects of the use of that material for engineered fill and cemented paste backfill.

Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and received an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). As described in Chapter 3 of the DEIR, underground exploration would take place after mine dewatering is complete and throughout the life of the mine. Exploration would be done primarily with diamond core drilling throughout the mine area. Exploration would produce core samples that would be brought to the surface for analysis to determine future mining areas.

## Response to Comment Grp 7-177

The commenter asserts that the discussion in the Project Description, Section 3.7 of the DEIR, regarding water treatment does not include adequate discussion of treatment methods, constituents of concern and water quality standards for the discharge. However, section 3 of the DEIR presents the Project Description; it is not intended to provide any engineering design details, analysis of project effects, or data that supports the analysis of potential effects. The water quality discharge standards are disclosed in the EIR, in Table 4.8-2 on page 4.8-44. The narrative on pages 4.8-42 through 4.8-45 of the EIR discusses the treatment requirements and summarizes

the treatment methods to be used along with permitting requirements for the discharge. Appendix K.4 of the DEIR contains the Water Treatment Plant Design Report.

Mitigation Measure 4.8-1(a) requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. The NOI shall include evaluation of potential constituents of concern and demonstrate that water treatment plant (WTP) design shall successfully treat mine water to meet the water quality standards and treatment goals. Please see Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 7-178

The commenter states that a monitoring plan should be required. A mitigation monitoring and reporting program will be required to enforce all mitigation measures imposed in the DEIR. With regard to water quality mitigation, Mitigation Measure 4.8-1(a) requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be received before initial mine dewatering can begin. The NOI will include water monitoring requirements for the permitted discharge. Please see Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 7-179

The commenter asserts that the information provided in the Project Description is insufficient regarding impacts from cemented paste backfill; however, Section 3 of the DEIR presents the Project Description; it is not intended to provide any engineering design details, analysis of project effects, or data that supports the analysis of potential effects. Discussion of the placement of CPB and the potential impacts of its use are provided in Chapter 4.8 of the DEIR, on pages 4.8-46 through 48-49. Section 4.4.2 of Appendix K.2 discusses and presents the results of DI-WET leach testing and acid-based accounting performed on four tailings samples (from which the mine backfill would be derived) for the project and Section 4.4.3 discusses the use of Portland cement in cemented paste backfill. Portland cement use of 25 tons per day (5% cement content in cemented paste fill) is assumed for the project as disclosed on page 295 of Appendix E.1. The grind size of the tailing's samples tested ranged from 80% passing 75 microns to 300 microns as discussed in Appendix H of Appendix K.2. The historic grind of ~80% passing 190 micron is assumed for the geotechnical study presented in Section 5.1.1 of Appendix H.1.

The "Desktop Study of Cemented Paste Backfill, ITASCA Denver, Inc. February 24, 2020." discusses in detail the tests on leaching characteristics performed for the project and concludes: "Based on the testing results described herein, Idaho-Maryland Mine flotation tailings have low sulfide content, are net acid-neutralizing, have solid-phase metals contents that are comparable to the average crustal abundances, and have leachate concentrations from WET-DI tests that meet all California primary MCLs. Thus, it is likely that the CPB used in the Idaho-Maryland Mine will have very low solute release rates and will be generally environmentally benign.

## Response to Comment Grp 7-180

The commenter asserts that the DEIR does not include adequate sampling of rock to analyze water quality impacts from engineered fill placement, as compared to international standards. Please see Response to Comment Grp 7-177 and see Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 7-181

The commenter asserts that there is not sufficient engineering detail to ensure the engineered fill pads will be stable. However, engineering level detail is not required in an EIR. (Dry Creek Citizens Coalition v. County of Tulare (1999) 70 Cal.App.4th 20, 26.) The geotechnical engineering reports (Appendix H.1 and H.4 of the DEIR) provide specific grading recommendations for placement of mine waste as engineered fill in thin, horizontal lifts (layers). The new mine waste will not be placed on old mine waste or other existing fill unless the existing mine waste and fill is first reworked as engineered fill pursuant to the geotechnical engineering recommendations. The commenter may have misinterpreted the diagonal hatch pattern in the Rise drawings as represented end-dump layers. The hatch pattern does not represent the placement method and has nothing to do with the technical specifications for construction of engineered fill. The engineered fill is to be placed and compacted in thin horizontal lifts pursuant to the geotechnical engineering reports.

## Response to Comment Grp 7-182

The commenter asserts that the seismic reports are not up to date and are inadequate because mine waste facilities need to withstand larger seismic events because of the long-expected life of the water facilities. The engineered fill will be composed of barren rock and dewatered tailings. No tailings ponds or "water facilities" for storage of mine waste are proposed. NV5 evaluated seismic risk and states on page 12 of Appendix H.1, "Based on our site observations, the geology of the region and our experience in the area, our opinion is that the risk of seismically induced hazards such as slope instability, liquefaction, and surface rupture are remote at the subject site."

The commenter also asserts that the description of the tailings in the geotechnical report for the Centennial site is inadequate. As stated on page 12 of Appendix H.1, the gradation similar to historic tailings gradation was assumed for analysis in the geotechnical report. The historic grind of ~80% passing 190 micron is shown to result in high gold recovery (97.2%) in metallurgical testwork provided in Appendix H of Appendix K.2. This assumption is representative of the tailings that will be placed as part of engineered fill.

## Response to Comment Grp 7-183

The commenter asserts that the DEIR does not explain how tailings and waste rock will be blended to create engineered fill pads. However, NV5 provides recommendations for blending of rock and tailings on page 14 of appendix H.1 to the DEIR.

## Response to Comment Grp 7-184

The commenter asserts that the likelihood of selling rock and tailings as construction aggregate is low because of potential sulfide contamination and liability issues. As explained in Section 4.4.1 of Appendix K.2, Sample MAA-1, which is the sample cited by the commenter as having 1.78% sulfide, is altered meta-andesite and this type of rock is expected to be a minor component of all materials produced (12 tons per day). Most of the underground work that would occur as part of the project would be tunneling to access the ore deposit and to provide access routes to move material and provide ventilation. These workings would be almost exclusively within barren meta-andesite rock that has low sulfide. As shown in Table 4-8 of Appendix K.2, samples MA-1, MA-1, MA-3 represent the unaltered meta-andesite rock where most tunneling would take place. For these unaltered meta-andesite samples, Sulphur HNO3 ranged from 0.02% to 0.27%. Tailings samples F-1 through F-4 ranged from 0.04% to 0.06%. As such, most of the rock produced by the project would not have significant sulfide content and would be suitable for use as construction aggregate.

## Response to Comment Grp 7-185

As described in Section 3.0 of the DEIR, after full placement of fill at the Centennial and Brunswick Industrial sites to the pad design elevations hauling of engineered fill (barren rock and sand tailings) would shift entirely to be utilized in local and regional construction markets. With regard to storage of fill material on-site, please see Master Response 11 – Engineered Fill Utilized in Local and Regional Construction Markets. No stockpiles of fill material are proposed on-site.

## Response to Comment Grp 7-186

As discussed on page of Appendix K.2 of the DEIR, the restoration of the post-mining discharge through the drains would be comparable to existing conditions and, thus, not an impact under CEQA. However, once the mine discharge from the drains resumed, compliance measures may be required by RWQCB to address the Basin Plan, antidegradation, and other water quality standards. These measures might include sealing off areas of the underground workings that are the primary source of arsenic in the existing drain water, sealing the underground workings sufficiently to prevent seepage of water from the connected mine workings, obtaining an Individual NPDES permit upon closure, or treating of the mine water seeps after closure.

Mine water discharge is not part of the reclamation plan requirements of the California Surface Mining and Reclamation Act (SMARA); however, there will be water quality specific financial assurances for closure and post-closure maintenance of mining units as required by Title 27 section 22510. This may include the need for long-term water treatment of mine-related discharges. This issue will be addressed in the approval of the WDRs required by Mitigation Measure 4.8-1(d) and 4.8-1(e)).

## Response to Comment Grp 7-187

The commenter asserts that the Union Hill Mine may have hydraulic connection to the Idaho-Maryland Mine and flooding may result. The Union Hill mine is discussed in Section 3.3.3.4 of Appendix K.2 of the DEIR. The Union Hill mine is a smaller mine than the others in the project area. It was closed in 1918 and has been flooded with water since that time. The Union Hill mine is not connected to any of the other underground mine workings in the area but is in close proximity to the workings of the Brunswick Mine. On April 17, 2019, the water level in the Union Hill shaft was 165 feet higher than the water level in the New Brunswick shaft. The Union Hill mine workings are within 95 feet to 180 feet of workings of the Brunswick Mine at three to four different levels. The Brunswick mine tunnels in proximity of Union Hill were constructed around 1950. During the post WWII period, the combined Idaho-Maryland Mine workings were completely dewatered. In 1956, the water level at the Union Hill Mine was reported to be within 20 feet of the top of the shaft, suggesting that the complete dewatering of the adjacent mine workings resulted in no more than 10 to 20 feet of water level decline in the Union Hill Mine.

A “conduit” has not formed between the mines in the previous 70 years, which included active mine operations, as evidenced by the different observed water levels. The proposed mine pumping and treatment system, with a maximum capacity of 2,500 gpm has significant excess capacity over maintain dewatering needs. Any necessary safety procedures or measures relating to flood risk would be regulated by the Mine Safety and Health and Administration (MSHA).

## Response to Comment Grp 7-188

The commenter asserts that the drill hole intervals were not included in the DEIR’s analysis. However, the drill hole intervals and locations where this material is derived are shown on Sheets 5-7 of Appendix K.2 to the DEIR.

## Response to Comment Grp 7-189

Section 4.4.2 of Appendix K.2 discusses and presents the results of DI-WET leach testing on four tailings samples for the project. The grind size of the tailing's samples tested ranged from 80% passing 75 microns (Sample F-1) to 300 microns Sample (F-2) as discussed in Appendix H of Appendix K.2. The historic grind of ~80% passing 190 micron is provided in Section 5.1.1 of Appendix H.1 and shown to result in high gold recovery (97.2%) in metallurgical testwork provided in Appendix H of Appendix K.2. The DI-WET leaching results as shown in Table 4-7 of Appendix K.2 shows that metal leaching from tailings samples is low for all grind sizes including for Sample F-1 which was ground significantly finer than the historic grind size.

Engineering level detail is not required in an DEIR. (Dry Creek Citizens Coalition v. County of Tulare (1999) 70 Cal.App.4th 20, 26.) Even without that detail, the DEIR concludes that the effect of the proposed actions on water quality could be significant. The mitigation measures identify the steps that must be taken to reduce the potential impacts to less than significant. The engineering details described in this comment would be developed through the mitigation measures.

## Response to Comment Grp 7-190

The commenter states that a different leach testing method should have been used on the tailings and waste rock samples. As discussed below, the method of testing the rock was appropriate under California standards.

The California Waste Extraction Testing (WET) method was used to determine the amount of extractable substance in waste rock (CCR Title 22 Division 4.5, Chapter 11, Article 5, Appendix II).

The Central Valley Regional Water Quality Control Board (CVRWQCB) has prepared the guidance document: The Designated Level Methodology for Waste Classification and Cleanup Level Determination, Updated June 1989. https://www.waterboards.ca.gov/centralvalley/plans_policies/guidance/dlm.pdf

Page 24 of the guidance document states that the results of the acid-base accounting would indicate which extraction solution should be used in the WET. The citrate buffer is appropriate for any waste which has an ANP to AGP ratio of less than 3:1. Deionized water could be substituted for the citrate buffer for wastes having an ANP to AGP ratio of 3:1 or greater.

As shown in Table 4-8 of Appendix K.2, the ANP to AGP ratios for all samples except for MAA-1 are greater than 3:1 and the use of distilled water is appropriate under the guidelines. A citrate buffer should have been used for sample MAA-1. However, this is a minor component of the barren rock and further testing will be required in the RoWD/WDR process.

Section 3.3.4 of the Designated Level Methodology Guidelines defines the Soluble Designated Level (SDL) for a constituent of a solid waste, expressed in milligrams of constituent per liter of extract from the Waste Extraction Test (mg/l of WET extract) is equal to: Water Quality Goal (mg/l) x Environmental Attenuation Factor ÷ 10. The technical report, Appendix K.2 of the DEIR compares the WET result directly to water quality goals in its discussions are therefore implies the assumption of 10 for the environmental attenuation factor. This is likely a conservative assumption as a "generic" environmental attenuation factor of 100 would more typically be assumed to make a preliminary assessment of how waste will be classified. (See page 32 of the Designated Level Methodology Guidelines)

Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and received an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). The waste characterization and required testwork may include using kinetic testing. Please see Master Response 8 – Mine Waste Characterization.

As the commenter notes, WET results for aluminum presented in Table 4-7 are generally higher than the screening levels and low threat discharge permit limits presented in Table 4-10 of Appendix K.2. The total content of aluminum in the samples are not unusual and range from 421 to 41,300 mg/kg. This is significantly lower than the average crustal abundance of aluminum of 83,600 mg/kg (See Table 3 of Itasca Desktop Study of Cemented Paste Backfill). As discussed above, the potential impact of aluminum to water quality would be thoroughly investigated during the RoWD/WDR process required by Mitigation Measures 4.8-1(d) and 4.8-1(e). Any monitoring requirements would be specified in the approved WDR.

## Response to Comment Grp 7-191

The commenter asserts that antimony should be monitored in the mine discharge water. WET results for antinomy presented in Table 4-7 are higher in samples MAA-1 and MS-1 than the screening levels and low threat discharge permit limits presented in Table 4-10 of Appendix K.2. The total content of antimony in these samples is also elevated. However, the lithologies represented by these samples are expected to be a minor proportion of barren rock (15 tons per day) produced by the project as explained in Section 4.4.1 of Appendix K.2. Any monitoring requirements, including monitoring for antimony, would be specified in the approved WDRs.

## Response to Comment Grp 7-192

WET results for arsenic presented in Table 4-7 are higher in sample MAA-1 and MS-1 than the screening levels and low threat discharge permit limits presented in Table 4-10 of Appendix K.2. The total content of arsenic in these samples is also elevated. However, the lithologies represented by these samples are expected to be a minor proportion of barren rock (15 tons per day) produced by the project as explained in Section 4.4.1 of Appendix K.2 to the DEIR. Any monitoring requirements, including for arsenic, would be specified in the approved WDRs.

## Response to Comment Grp 7-193

WET results for copper presented in Table 4-7 are higher in tailings samples F-3 and F-4 than the screening levels and low threat discharge permit limits presented in Table 4-10 of Appendix K.2. The total content of copper in the samples tested are not unusual and range from 27 to 141 mg/kg. This is similar to the average crustal abundance of copper of 68 mg/kg (See Table 3 of Itasca Desktop Study of Cemented Past Backfill). Any monitoring requirements, including for copper, would be specified in the approved WDRs.

## Response to Comment Grp 7-194

As discussed on page 116 of Appendix K.2, water currently within the flooded mine workings has low dissolved oxygen (DO) levels, creating reducing conditions (low or no dissolved oxygen present and negative oxygen reducing potential). The low oxygen levels and reducing conditions prevent the oxidation of sulfide minerals, such as pyrite, that are exposed within the surfaces of the underground workings.

Please see Response to Comment Grp 7-190 regarding the use of deionized water in WET testing.

Any monitoring requirements, including for iron and manganese, would be specified in the approved WDRs.

## Response to Comment Grp 7-195

The commenter states that nitrate will be higher than expected in mine water discharge. As discussed on page 4.8-48 of the DEIR, the primary residual components of the ammonium nitrate-fuel oil (ANFO) used for blasting, ammonia and nitrate, are very soluble and mobile in water. This means that any blasting residuals would be continually removed from the mine over time through the dewatering system. The proposed WTP is designed to treat ammonia and other blasting residuals that might occur due to incomplete detonation. Thus, when the mine is allowed to flood again following the completion of mining, there is no reasonable potential that residuals from former blasting activities would cause a violation of any water quality standards or waste discharge requirements or otherwise substantially degrade surface or groundwater quality. As stated on page 4-5 of Appendix K.4, low concentrations of NH3 may occur as a result of explosives used during periods of active mining and will be removed by the aeration process. If required, the efficiency of this aeration can be enhanced by increasing the pH. This will generate more of the gaseous form of NH3 which can be stripped from the water. Therefore, as a contingency component for Fe (and Fe/As), Mn, and ammonia treatment, sodium hydroxide (NaOH) will be included in the permitting efforts for pH adjustments should it become necessary to add alkalinity to the water for Fe (along with Fe/As) and Mn treatment, or to treat NH3 more efficiently or in higher concentrations than have been previously detected. In regard to ammonia treatment, this may occur as a result of explosives used during periods of active mining. Also see Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 7-196

The commenter states that sulfate will be higher than expected in mine water discharge, but does not provide any evidence of that statement. Monitoring requirements for sulfate would be specified in the approved WDRs.

## Response to Comment Grp 7-197

The commenter states that sulfide-sulphur is not reported on a per-sample basis. The purpose of the acid-base accounting (ABA) analyses is to identify the total acid generation potential and the total acid neutralization potential. However, the presence of individual sulfur forms for each sample analyzed is shown in Table 4-8 of Appendix K.2.

## Response to Comment Grp 7-198

Mitigation Measures 4.8-1(d) and 4.8-1(e) requires submittal of a RoWD and approval of WDRs, which will address monitoring requirements and identify constituents of concern. The CVRWQCB will select the appropriate continents that require monitoring, which may include antimony, copper and nitrate as requested by the commenter.

## Response to Comment Grp 7-199

The commenter states that leach tests for cement paste backfill need to be completed. The "Desktop Study of Cemented Paste Backfill, ITASCA Denver, Inc. February 24, 2020" discusses in detail the tests on leaching characteristics performed for the project and concludes: "Based on the testing results described herein, Idaho-Maryland Mine flotation tailings have low sulfide

content, are net acid-neutralizing, have solid-phase metals contents that are comparable to the average crustal abundances, and have leachate concentrations from WET-DI tests that meet all California primary MCLs. Thus, it is likely that the CPB used in the Idaho-Maryland Mine will have very low solute release rates and will be generally environmentally benign."

Mitigation Measure 4.8-1(d) requires the applicant to submit a Report of Waste Discharge (RoWD) and received an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill, so additional testing will be done as requested by the commenter.

## Response to Comment Grp 7-200

The Commenter asserts that the DEIR has a fundamental lack of information on the economic viability of the mine, and potential environmental impacts related to geochemistry and water quality. Geochemistry and water quality are addressed in detail in Chapter 4.7, Hydrology and Water Quality, of the DEIR, and the accompanying technical reports, namely Appendix K.2 of the DEIR. The economic viability of the mine is outside the scope of CEQA.

Based on the Commenter's above summarized assertion, he states the DEIR should analyze an alternative that provides for dewatering and underground exploration without allowing for mining. This proposed alternative is not economically feasible because there is significant cost with dewatering the mine, including construction of a water treatment plant, installation of a potable water pipeline to provide water to affected well owners, and underground access and safety improvements necessary to complete the suggested exploration phase. The proposed alternative would be economically infeasible because all the above costs would be incurred without the ability to produce any valuable minerals to offset that cost. Additionally, the proposed alternative would not meet the first project objective, which is "Construct a commercially viable, financeable, major underground gold mine operation that will produce 1,000 tons per day (365,000 tons per year) of gold mineralization." As the proposed alternative does not meet the first project objective and would be financially infeasible, the alternative is rejected from further consideration.

Re: Comments on the Draft Environmental Impact Report (DEIR) for the Idaho-Maryland Mine Project (Project, Mine)

Note documents cited and submitted under separate cover:

- Baseline Environmental Consultant Report, Feb 15, 2022 (Baseline).
- Salter Report, March 9, 2022 (Salter).
- Comments on the Draft EIR for the Idaho-Maryland Mine Project - 16Mar22, Center for Science in Public Participation (CSP2).

**Grp 8-1**

Our review of the DEIR has identified significant issues regarding the adequacy, completeness, and conclusions of the report.

## Aesthetics

**Grp 8-2**

Images of the facilities presented in the DEIR are not a fair representation of the actual visual character of the project; consequently, the DEIR understates the Project's visual impacts. The perspectives reduce the perceived size of the structures, and the viewpoints are often restrictive in terms of providing a full view. To provide an accurate representation of the project, the revised DEIR must provide better viewpoints that preserve a 1:1 accuracy with the true width to height ratios of the structures.

**Grp 8-3**

The use of an "erosion control seed mix" for reclamation of the mine waste piles will create the image of a dead zone, especially during the dry seasons. Native vegetation including deciduous and evergreen bushes and trees should be required as a mitigation to reduce the stark contrast between the disturbed site and the normal (current) vegetation.

## Air Quality

**The DEIR provides no evidence that the project's long-term NOx, ROG, and PM10 emissions will be mitigated to a less-than-significant level.**

**Grp 8-4** The DEIR fails to adequately mitigate the Project's air quality impacts. It relies on a bare minimum of mitigation measures recommended by the Northern Sierra Air Quality Management District (NSAQMD) to address air quality impacts, and these measures only address emissions during a one year period of construction. As we explain below, construction will certainly last longer than one year. In addition, the mitigation measures do not address the long-term emissions that will result from 80-years of mining operations associated with the Project. As a result, there is no evidence that the Project's long term emissions have been mitigated to a less-than-significant level, as concluded by Baseline Engineering Consultants (Baseline).

The revised DEIR must identify feasible and effective mitigation measures that address emissions from 80-years of mining to ensure that emissions are kept at less-than-significant levels. Otherwise, the EIR must identify these long term impacts as significant and unavoidable.

**Mine exhaust moisture creates potential air quality, hazard, and aesthetics impacts.**

The DEIR provides no information about the potential obstruction of the airspace surrounding the airport. (See also, "MineExhaustMoisture, attached as a reference to this letter). The Loma Rica Drive Industrial Area Plan states:

**Grp 8-5** "Any proposed object or structure which would penetrate any imaginary surface is considered by the FAA to be an obstruction to air navigation and requires an FAA aeronautical study to determine whether a potential obstruction will have a substantial adverse effect upon the safe and efficient use of navigable airspace by aircraft." (Loma Rica Drive Industrial Area Plan, May 27, 2008, p38-39)

Although the DEIR does not disclose it, the mine ventilation system would discharge 200,000 cfm of saturated air at 68F degrees from the top of the headframe with an upward velocity of 7.7ft/sec. (DEIR Appendix E.1_AQ-GHG Report (p371 of 1938) ) The headframe is located within the Loma Rica Airport Safety Zone 5. Under some weather conditions, the large volume of air exhaust may form a persistent cloud plume or fog. In addition, the large mass of air moving upwards may create turbulence, also a potential hazard. These are potentially significant and unavoidable impacts..

**Grp 8-6**

**Grp 8-7** This plume and associated fog as well as the tall headframe will also result in potentially significant visual impacts in this rural area where this type of view is not expected.

**Grp 8-8** The revised DEIR must evaluate the following relative to the headframe and moisture emissions:

- When will these conditions be present and to what extent?
- What are the aesthetic and aircraft hazard impacts?

2

## Air Quality

**Management of safeguard controls for asbestos is inadequate.**

(See "ASUR Plan Analysis.pdf", attached as a reference to this letter. Portions of that document are summarized here.)

**Grp 8-9** The plan described in the DEIR for managing asbestos-laden mined materials is inadequate. Asbestos is likely to be released during underground blasting, crushing, and ore processing. It also is released during material handling, on-road transport, placement grading and compaction. The DEIR states that the Asbestos Management Plan would ensure that average mined material and engineered fill contains less than 0.01% asbestos. (DEIR 3-20) Testing the asbestos content, however, does not control the amount of asbestos in the actual material mined. To control the average amount of asbestos in output materials (and to avoid significant impacts related to asbestos exposure), the DEIR must ensure that asbestos levels do not exceed this threshold. Currently, the DEIR does not include any evidence that asbestos levels will not exceed this threshold.

**Grp 8-10** The testing process may require up to two weeks before the results are known, yet the Project calls for daily mining activity to continue during this time. This daily mined material would have to be stockpiled while awaiting the test results, which could expose workers to dangerous levels of asbestos. The DEIR does not disclose this fact nor does it analyze the associated impacts.

**Grp 8-11** In addition, if the running average of asbestos in the daily mined material exceeds the required threshold, batches containing higher asbestos levels would have to be stockpiled in order to be later paired up with batches having lower asbestos levels. The DEIR does not disclose this fact nor does it analyze the associated impacts or recommend mitigation measures.

**Grp 8-12** The mineral processing described in the DEIR does not address the need for stockpiling materials or address the likely impacts of such efforts. The Asbestos Management Plan provided in the revised DEIR must detail all of the steps necessary to carry out the correct management of this hazardous waste, including the location and organization of stockpiled materials, and adequate safeguards to avoid fugitive dust emissions and potentially hazardous conditions.

These deficiencies point to potentially significant and unavoidable impacts and must be analyzed in the DEIR.

**The management of fugitive dust after it leaves the mining facilities is inadequate.**

**Grp 8-13** In 1986, asbestos was identified by the California Air Resources Board (CARB) as a TAC. CARB also determined that there is not enough scientific evidence to identify an asbestos threshold level below which no significant adverse health effects are anticipated (17 CCR 93000,Implementation Guidance Document 2017, CARB pg 1) (See Health Risk Assessment Critique (HRA Critique), attached as a reference to this document.)

As a TAC, asbestos, as well as respirable crystalline silica, fall under the non-criteria air pollutant category because they lack an identified safe "threshold level below which no significant adverse health effects are anticipated." There are no established limits for monitoring emissions of non-criteria

3

air pollutants, silica and asbestos, into the ambient environment. The Health Risk Assessment is based on 30 years of exposure, so the cumulative effects from 80 years have not been addressed. Both silica and asbestos are inert substances not subject to environmental degradation that will have potential impacts beyond the 80-year project permit (HRA Critique).

The revised DEIR should establish asbestos mitigation protocols and robust monitoring systems of waste rock during transport and disposal to ensure the protection of workers and the public from the adverse health effects associated with the TACs, asbestos, and respirable crystalline silica. Without identifying clear and achievable mitigation measures, the DEIR must identify this as a significant and unavoidable impact.

**The DEIR Health Risk Assessment used invalid meteorological data to determine emissions and should be redone.**

Grp 8-14

Toxic Air Contaminants (TAC) are toxins which may cause or contribute to an increase in death or serious illness from cancer and other acute or long-term diseases. TACs may cause health damage even at extremely low levels, and are found in, among other items, vehicles, off-road equipment, blasting emissions, and fugitive dust sources. (HRA Critique)

TAC ingredients include particulate matter from diesel emissions, asbestos dust, silica dust, heavy metals, ammonium nitrate fuel oil, hexavalent chromium, and radon – all of which will be produced by mining activity, and which can become airborne, traveling on wind currents toward population centers around Nevada County.

Many establishments are located within a two mile radius of the mine including the hospital, assisted living facilities, health centers, physicians' offices, non-profit organizations, business parks, county offices, shopping centers, apartment complexes, and hundreds of private residences. TAC releases from the mine have the potential to adversely impact these receptors.

In Nevada County, the mortality rate from Chronic Lung Disease is already – without the added toxic emissions from the mine – double the statewide rate. Nevada County also has higher-than-state-average levels of air pollutants, ozone and particulate matter, radon, chronic disease, an aging population, and poverty. Given the extent of health risk to so many and so wide a range of people, the DEIR's health risk assessment is completely inadequate.

The HRA relies on questionable assumptions. The model relies on meteorologic input data, with the quality, quantity, speed, and direction of travel of the air toxins dependent on these meteorological factors. Yet the meteorological data input used by Rise comes from a Blue Canyon site - not from a Grass Valley site - an area with a significantly different meteorological profile than that of Grass Valley.

Blue Canyon, located on Highway 80, bears little meteorologic resemblance to Grass Valley: it notably deviates from Grass Valley in elevation, temperature, rainfall, snowfall, wind speed, and wind

direction. Using Blue Canyon's meteorologic data will not correlate with Grass Valley meteorologic data under any circumstance, making any TAC statistic invalid.

Therefore, the DEIR's Health Risk Assessment must be revised using valid meteorological data, in order to accurately assess the potential health impacts of the mine's toxic air. Once the HRA is revised, the DEIR must also be revised and recirculated for public review and comment.

**Radon levels need adequate assessment.**

**Grp 8-15**

The DEIR does not disclose the background radon level of all homes and properties near the project. The DEIR also does not disclose the effect that dewatering or mining operations including blasting will have on radon levels. Nor does it describe the effect that mining operations will have on radon levels.

It also does not explain whether blasting operations will increase radon and, if so, the environmental impacts of increased radon levels. The revised DEIR must provide a comprehensive analysis of radon-related impacts.

## Biological Resources

**Proposed mine dewatering activities have the potential to have asignificant impact on dependent biological resources.**

**Grp 8-16**

The DEIR fails to adequately address biological and aquatic resources, and hydrological impacts to those resources.

The DEIR's biological surveys exclude an entire reach of South Fork Wolf Creek (SFWC). Species of special concern are inadequately considered and qualitative data for benthic macro-invertebrates (BMI) is missing. (Wolf Creek Community Alliance (WCCA), Benthic Macroinvertebrate Analysis, 2007)

Aquatic resources are excluded through an inaccurate hydrological assessment of the full length of SFWC, ignoring the connectivity of the creek upstream and downstream of the culvert on the Mine property, thus failing to consider the movement of trout and other aquatic species.

**Grp 8-17**

Hydrological impacts due to mine dewatering into SFWC are inadequately studied, mischaracterized, or not considered. The initial dewatering rate of 2500 gallons per minute (gpm) would be followed by 80 years of subsequent operational dewatering at 850 gpm and as much as 2500 gpm. The DEIR fails to adequately consider this long-term higher rate of discharge. Nor does the DEIR consider the seasonality of stream flow, loss of streambed or streambank habitat, changes in temperature, differences in Specific Conductance (EC), and habitat for BMI. Drawdown of the water table due to dewatering is also underestimated and its impacts to meadow, wetland, and forest habitats are not considered. Further, the DEIR fails to consider chronic and cumulative impacts to BMI, trout, and other aquatic species, including special concern amphibians. (WCCA)

Overall, because the DEIR does not adequately address biological and aquatic resources or sufficiently analyze hydrological impacts, this document must be revised.

5

**Centennial Site - Biology**

Grp 8-18

**Removal of flora, fauna, topsoil, wetlands and overburden down to bedrock to prepare the Centennial site for mine waste dumping represents a significant impact.**

The Project calls for the removal of flora, fauna, topsoil, wetlands and overburden down to bedrock to prepare the Centennial site for mine waste dumping. The DEIR fails to adequately address impacts to these resources. It must be revised to provide this analysis.

**Baseline vegetation conditions are unknown.**

Grp 8-19

The DEIR is required to identify all special status species within 5 mi of the site. Note that the 5 mile radius map on Appendix F.3, page 33, is located in the wrong spot, approximately ½ mile from the site. The 5 mile zone must be corrected to include the correct area, and any additional species within that area must be identified.

The Draft RAP is still under review by the Department of Toxic Substances Control (DTSC) and thus the baseline conditions for the evaluation of biological and other impacts are based upon speculation. For example, the following statements are provided:

Grp 8-20

- Biological, vegetation communities: "...because it cannot be precisely established for the baseline condition given that the baseline has been adjusted to account for the separate remediation efforts that will be conducted..." (DEIR 4.4-3).
- Biological, aquatic resources: "...the exact acreages of each aquatic resource type cannot be precisely established for the baseline condition given that the baseline has been adjusted to account for the planned remediation efforts that will be..." (DEIR 4.4-10).

Grp 8-21

Approval of the Draft RAP by DTSC is uncertain. Consequently, the revised DEIR must use a baseline of "existing conditions."

**Wetlands will be unnecessarily destroyed.**

Grp 8-22

The Centennial RAP remediation requires placement of four feet of topsoil as cover material over the treated areas. The areas will then be revegetated. This is a temporary fix. Later, the topsoil will be removed and engineered fill from the mine operations will be placed on this area, forming the new mining operation's tailings pile.

As stated in the RAP draft, the topsoil for the RAP remediation will be coming from onsite "borrow" areas, and to obtain it, wetlands will be destroyed, a significant impact. However, the destruction of the wetlands could be substantially reduced by not removing the soil from those "borrow" areas. This is a feasible mitigation which must be discussed in the revised DEIR.

6

In addition, the DEIR fails to identify where the cover soil will be placed after the remediation is completed in order to begin placement of mine waste from the Project operations.

**Grp 8-23**

- Will it be stored on site? Where?
- Will it be hauled off site? Where?

The revised DEIR must disclose this information and must analyze the associated direct and indirect environmental impacts.

**Pine Hill flannelbush is not adequately protected.**

**Grp 8-24** The planned work to physically close the South Idaho Shaft and Tunnels on the Centennial site and the DEIR does not adequately document its phasing. This work is planned to take place before mine waste is dumped on the Centennial site and could conceivably be implemented prior to the DTSC Cleanup on that site. The DEIR fails to map the location of the shaft, tunnels, and all related work on the shaft as it relates to the Pine Hill flannelbush. The revised DEIR must analyze impacts to Pine Hill flannelbush caused by this phase of construction. Given the possibility that South Idaho work could proceed independently, and that the DTSC work could conceivably take place in conjunction with that work or be impacted by that work, the revised DEIR must include a clear work phasing plan to guarantee adequate protection of the flannelbush.

**Grp 8-25** Within the DEIR's "Appendix F.3_The Centennial Impact Tech Memo" and Appendix F.4_Centennial HMP Pine Hill flannelbush.pdf", and others, the phrase "should be avoided" is used repeatedly as a guidance for protecting biological resources. The word "should" is unenforceable. It must be corrected to "shall" or "must".

**Grp 8-26** The DEIR's Habitat Management Plan for Pine Hill flannelbush proposes to remove 18 plants. It also indicates that four plants are located within 30 feet of the edge of the engineered fill and could be impacted. The DEIR does not disclose why these 18 plants must be removed. The DEIR's mitigation should be revised to eliminate the need to remove these plants.

**Grp 8-27** The DEIR must also include information on the relocated re-establishment time required for transplanted plants, and site activity phasing must be provided to ensure that the re-establishment time is included.

**Grp 8-28** Impacts to the Pine Hill flannelbush as the DEIR is currently written are significant and unavoidable. The DEIR must be revised to evaluate these impacts and provide feasible and effective mitigation.

## Centennial Site

**Grp 8-29** **The DEIR does not adequately define the Mine Project to include the Centennial site and accordingly, fails to identify all potential impacts.**

The DEIR fails to adequately address impacts associated with the Centennial Industrial Site (Centennial). This site is the location of hazardous waste left over from past Idaho Maryland Mine operations. The DEIR assumes that the Centennial site will be cleaned up before the use of the site for

7

deposition of new mine waste. Yet the significant work which is needed to accomplish this clean-up is not disclosed nor evaluated in the DEIR. Rather, the DEIR assumes that the clean-up has already been accomplished, and uses the post clean-up conditions as the baseline for some of its environmental impact assessments.

The DEIR does not describe the current physical conditions of the Centennial site or include the necessary clean up of the existing contamination at that site as part of the Project because it assumes that Centennial will be cleaned up prior to the start of construction. As discussed above, the clean up for Centennial has not been approved by DTSC and it is unclear when DTSC might approve the clean up. Consequently, it cannot be excluded from this DEIR. As a result, any assumptions about baseline conditions for purposes of assessing impacts to the Mine Project are speculative at best, and at worst, significantly underestimate the actual impacts of the Project.

**Grp 8-29**

The current conditions of the Centennial site must be used as the DEIR baseline in order to meet the CEQA requirements for a full analysis of the impacts of the Mine Project. Moreover, the Centennial clean up should be included as part of the Project to address the whole of the action under CEQA. In order to accurately assess impacts, the existing conditions, or baseline, of the Project must be the current state of the Centennial site, not a speculative future condition.

The DEIR states that Rise intends to complete the site cleanup independently of the mine, but no final plans have been provided. Currently a Draft Remedial Action Plan (RAP) for the cleanup of the Centennial Site is being reviewed by the DTSC.

The assertion that Rise intends to complete the cleanup regardless of the status of the mine project is not credible. This statement was made to avoid addressing the impacts of the cleanup within the DEIR. It is clear that the RAP and the IMM Project are integrally related:

- The Draft RAP states that the site is being prepared for mine waste.
- The Draft RAP calls for preparing the site for mine waste, including removal of vegetation, removal of soil down to solid base to create a solid base for planned mine waste dumping.

**Cumulative impacts to groundwater will result from Centennial site cleanup.**

**Grp 8-30**

Groundwater recharge will be reduced by the proposed Centennial cleanup project as described in the Draft RAP. This is due to plans to move contaminated materials into the east portion of the site and cover with a cement and small aggregate (spread onsite and rotary mixed) impermeable layer of materials. In addition, the project would require that wetlands be removed. The DEIR fails to disclose that wetlands and marsh-like vegetation slow the surface flows and allow more water to percolate into the ground. The revised DEIR must take this into account when determining the project's effect on groundwater recharge combined with groundwater impacts from the remainder of the project.

**Grp 8-31**

Preparations for mine waste dumping is proposed to take place up to the boundaries for protected species, wetlands, and riparian setbacks. It is difficult for heavy equipment operators to perform tasks in close proximity to boundaries, and if excavation is involved, even hand work can create impacts. For example, on the Centennial site, the removal of top soil down to bedrock for mine waste dumping may involve pulling away of the supporting soil for protected areas. Soil can collapse from beyond the boundary, roots can be damaged, etc. The DEIR fails to analyze any of these impacts. The revised

8

DEIR must provide this analysis and identify feasible mitigation for these impacts. Mitigation must include, at a minimum, the establishment of an additional buffer zone between a protected area boundary and an allowed work area, with consideration of the particular activities governing the amount of buffering that is appropriate. This buffer zone must be mapped.

Nor does the DEIR disclose whether the soil, the vegetation, and the vegetation roots within the boundaries of the protected areas would be protected during excavation. It is imperative that excavation not cause soil loss or damage.

**Economic and Housing Impacts**

**Grp 8-32**

The mine will bring new employees, many of whom will likely be renters in the low and moderate income wage levels, worsening the already impacted housing market. Physical impacts can result from a tighter housing market: For instance, the numbers of middle and low income workers commuting into Grass Valley will increase. Also, the project may cause a trickle down effect of increased homelessness and a corresponding increase in homeless encampments in impacted wildland areas.

These issues and associated mitigation must be discussed in the DEIR. For example, mitigation should be identified to ensure that sufficient affordable housing is provided nearby for the project's employees.

## Hazards and Hazardous Materials

**Drawdown of groundwater within the mine workings may increase the potential for settlement or collapse of shallow workings which will affect individual property owners directly.**

When the water level in the mine workings is located near the ground surface, the drawdown of groundwater within the mine workings may increase the potential for settlement or collapse of shallow workings that were not formally closed. These issues are discussed in "DEIR Appendix H.6_Geotech Review of Near-Surface Features.pdf"

**Grp 8-33**

The building at 125 Spring Hill Drive sits on top of the Eureka Shaft. Though it was studied in 1985 and design recommendations for closing the shaft were produced, the actual method of closure is unknown. The DEIR provides no documentation or explanation about how these shaft closures will be carried out. Mine water is 35 feet down at the 125 Spring Hill Drive site. Though the DEIR states that the water is "likely in bedrock", it is not verified and dewatering could cause settlement or other damage.

The DEIR states that the mine applicant will "assist" businesses that sit atop mine works which may be affected by mine operations but the DEIR does not identify a financial assurance mechanism to compensate the landowners (including 125 Spring Hill Drive) if the dewatering causes damage or loss.

The Eureka Vertical Shaft is under the sidewalk and pavement at Spring Hill Dr and IM Rd. The water level is 17' below this location. Again, the DEIR does not identify any assurance that the City and/or land owner would be compensated if the dewatering causes damage or loss.

9

**Grp 8-34**

There is potential for sinkholes to occur where undocumented mine features may exist, particularly in areas where current mine water levels are closer to the surface. One example was some settlement caused by an unknown feature that was observed approximately 5 years ago approximately 100' South of the Idaho Pump Shaft (DEIR H.6, pg5)

**Grp 8-35**

The DEIR makes no clear statement of liability about what happens if historic mine works settle around the near surface features as a result of dewatering. This leaves private business and local government vulnerable to assume the costs from failed mine infrastructure. This is a potentially significant and unmitigated impact. The revised DEIR must provide a full analysis of these impacts and identify feasible and effective mitigation.

**Grp 8-36**

**The DEIR inadequately describes potentially hazardous waste rock and mine tailings management.**

As pointed out by Baseline Engineering Consultants (Baseline), the legacy contamination from prior mining indicates that the types of rock historically mined at the site contain heavy metals and, when excavated, these waste rock and mine tailings have been found to contain contaminants that pose a potential risk to people and the environment.

*"Neither the DEIR Project Description nor the Hazards and Hazardous Materials section adequately describes how future waste rock and mine tailings generated by the proposed project would be managed to ensure that they do not pose a health hazard to people or the environment (as the placement of similar waste materials from the same mine did in the past)" (Baseline).*

The revised DEIR must provide adequate information about the potential risks of the waste rock tailings and all potential impacts.

**Grp 8-37**

**Probabilities of collapse hazards are not adequately addressed.**

In evaluating the potential risks due to existing near surface features, the DEIR makes the following claim and is used as the basis for the scope of the report:

"In addition, the underground mine workings focused on removal of quartz vein materials that are generally narrow, so the collapse of a deep (e.g., 100 feet bgs) mine feature is not likely to be expressed at the ground surface."( DEIR Appendix H.6, pg 2).

Note that "not likely" is an ambiguous metric that can be satisfied by a less than 50% chance of occurrence. This is not the same as "there is No Potential for collapse". The DEIR does not disclose the following:

- The estimated likelihood of occurrence: Is it greater than zero?
- Whether the mine workings would be confined to narrow quartz veins.
- Mine works include voids due to tunneling, stoping, etc. Given that the mine works were in a fractured rock geology and may contain additional mine features such as stopes near surface but below 100', what is the justification for this 100' determination?

10

**Grp 8-38**

In addition, the DEIR fails to analyze the potential for collapse from all existing mine features. It also fails to evaluate the effects upon legacy mine works due to combined destabilizing activities such as dewatering, earthquakes, and use of explosives. The revised DEIR must provide these analyses.

**The DEIR's evaluation of seismic hazards due to faults and mining is inadequate.**

**Grp 8-39**

The mine project would target potential ore bodies that are more or less bounded by the Morehouse fault, the 6-3 fault (Weimar), and the Idaho fault, as well as numerous lesser faults. While the faults in this area are designated as being in a type C fault zone, with low seismicity and a low rate of recurrence, the DEIR does not analyze the effect that a seismic event would have on the mine or workers in the mine. (See FaultingHazards, attached as a reference to this document.)

Throughout the 80 year life of the proposed project, expansion of mine works will remove 30 million tons of rock mass, and change the overall competency of the surrounding bedrock. In addition, several million tons of mine waste will be positioned over or near the faults. Finally, at the end of mine operations, the mine will re-flood, leading to an additional potential increase in seismic activity due to the re-introduction of hydrostatic pressures (FaultingHazards).

**Grp 8-40**

The seismic reports discussed in the Geology section of the DEIR are not up to date and, even if updated, would not meet the requirements for a probabilistic seismic site analysis. (CSP2, p7)

The revised DEIR must include a complete and comprehensive analysis of the potential hazards due to seismic activity as a result of the Mine Project.

**Potential mine flooding and worker safety from groundwater occurrence in mine workings.**

**Grp 8-41**

In the DEIR's discussion of the Union Hill Mine, it is noted, "The Union Hill Mine workings are within 95 feet to 180 feet of workings of the Brunswick Mine at three to four different levels. During the post WWII period, the combined Idaho-Maryland Mine workings were completely dewatered. In 1956, the water level at the Union Hill Mine was reported to be within 20 feet of the top of the shaft, suggesting that the complete dewatering of the adjacent mine workings resulted in no more than 10 to 20 feet of water level decline in the Union Hill Mine."

There are two important points to note in this discussion, (1) the Union Hill Mine is very close to the Idaho-Maryland at several levels; and, (2) there has been a possible weak hydraulic connection between the two mines, which is only logical.

There is no discussion in the DEIR of the potential impacts for the Idaho-Maryland Mine if flooding were to occur during mining. According to ITASCA's report (DEIR Appendix K.3, Figure 2-3), there are extensive abandoned mine workings above and adjacent to the Idaho-Maryland Mine that would remain flooded after the Idaho-Maryland is dewatered. If a conduit between these two mines were to open, for instance due to the widening of a fracture related to blasting vibrations or a seismic event, the flood of water into the Idaho-Maryland could be rapid and catastrophic for anyone working in the mine.

11

The DEIR must be revised to evaluate the potential risks of flooding during mining operations, including potential risks to mine workers. (CSP2)

## Greenhouse Gas Emissions

**The DEIR relies on an arbitrary threshold for greenhouse gas emissions.**

**Grp 8-42**

The DEIR states greenhouse gas (GHG) emissions from mine operations would be just under 10,000 metric tons (MT) of GHG carbon dioxide equivalent ( CO2e) per year. This number was chosen as a bright line threshold based on other air districts in California that included Placer County, Sacramento Metropolitan Area, the Bay Area and Southern California. Neither the Northern Sierra Air Quality Management District (NSAQMD) nor the County have adopted numerical thresholds of significance for GHG emissions that would apply to the Project. The DEIR does not discuss the justification provided by each air district for adopting the 10,000 MT CO2e per year threshold, nor does it provide substantial evidence for applying this threshold to the project to demonstrate how it will achieve a fair share of the statewide GHG reductions goals for 2030 and beyond.

The DEIR must be revised to identify and provide justification for a GHG threshold of significance that will achieve the statewide GHG reductions goals for 2030 and beyond over the proposed 80 year lifetime of the mining permit. (Baseline)

**The DEIR underestimates GHG emissions from haul trucks.**

**Grp 8-43**

The DEIR states that the Centennial Industrial Site will be used for mine waste dumping to form "engineered fill" during the first 5 years of mine operations. The DEIR's analysis assumes that the Centennial Site remediation to remove toxic mine waste would be completed before the mine opens. However, since the remediation of the Centennial Site is not included in the DEIR analysis and, as indicated in the Project Description, may not be completed in any specified timeframe, "...it is speculative at best to assume that the Centennial Industrial Site will be available for fill placement." (Baseline)

To accurately account for the Project's GHG emissions, the DEIR should have assumed an additional five years of off site hauling at the beginning of operations. This additional hauling would generate significantly more emissions than disclosed in the DEIR. This also holds true for criteria air pollutants as well.

The GHG emission should be updated in the revised DEIR to include the prospect of the Centennial Site being unavailable for mine waste dumping.

**Mining energy requirements would eliminate gains attained through the Nevada County Energy Action Plan.**

**Grp 8-44**

The Nevada County Energy Action Plan calls for a 51% reduction in GHG emissions for electricity use by 2035, which is in close alignment with state goals. The Plan calls for residential energy reduction savings from building efficiency of 42 million kilowatt hours per year ( kWh/Yr).

12

The DEIR states the amount of electricity required to operate the mine would be approximately 49 million kWh/Yr (DEIR p. 4.3-59), which would erase any residential electricity savings attained by the Plan.

The total non-residential electricity use of the county in 2017 was 53 million kWh/Yr. So, GHG emissions from this one mining project alone would almost equal all other non-residential electricity use in the County and wipe out the projected 9 million kWhYr non-residential building efficiency savings.

Asking residents and business owners to cut down on their use of electricity while allowing the GHG emissions from the mine would be highly counter-productive and unfair. The DEIR must explain how the project intends to comply with the emission goals of the Nevada County Climate Action Plan.

The California Air Resources Board 2017 Climate Change Scoping Plan stated: "Achieving no net additional increase in GHG emissions, resulting in no contribution to GHG impacts, is an appropriate overall objective for new development." Given these facts, the DEIR must establish a net zero threshold for new GHG emissions from the Project and declare the project has significant and unavoidable impacts.

**Cement manufacturing is not included in the DEIR's GHG analysis.**

Cement manufacturing is a significant GHG source. The DEIR does not provide adequate information about the amount of cement that will be used for the cement paste backfill (CPB). Nor does it include GHG emissions from CPB. Based upon the number of cement truck trips, (468 trips/year, DEIR 4.3-53) and an 8 cubic yard payload of 9.2 metric tons, the emissions can be estimated.

**Grp 8-45**

The national weighted average carbon intensity for cement production is estimated at 0.97 metric ton $CO_2$/ton cement. Thus, each cement truck would contain cement that released about 8.3 metric tons of $CO_2$ when it was produced. Operationally, 468 truck trips would mean 3,884 metric tons of $CO_2$ were released in a year of cement production for the mine.

Therefore, the amount of cement manufacturing needed to create the CPB with 500 tons of rock waste per day constitutes a major GHG source contributing emissions on the order of 3800 metric tons per year of GHG $CO_2e$. The energy and environmental impacts of cement production used in the project should have been included in the DEIR.

The revised DEIR should provide adequate information to quantify these GHG emissions.

**Grp 8-46**

In addition, following initial onsite ore processing using sulfide flotation, the resulting gold concentrate would be shipped off site for further processing to extract the gold. The full energy and environmental impacts of further offsite transport and gold processing are not part of the DEIR and should have been included.

13

## Hazardous Materials

**Provisions for temporary storage of explosives on the surface are inadequate.**

**Grp 8-47** Several years of construction activities will require explosives prior to the construction of the longer term explosive storage facilities underground. Explosives will be needed for the construction of the new access shaft, reclamation of existing mine works, and development of storage areas and waste rock processing areas. The revised DEIR must identify the quantity, type and management of early phase explosives during construction.

**The DEIR's emergency evacuation analysis is inadequate because it only discusses the haul trucks but not trips associated with the mine's employees.**

The DEIR's analysis (Section 4.7-4) of emergency evacuation impacts is inadequate. For example, it focuses on haul trucks but fails to analyze the effect the evacuation of mine employees would have on the emergency evacuation of area residents.

**Grp 8-48** The DEIR, Table 3.8, "Operations Workforce", shows there will be 111 employees per shift adding roughly an equivalent number of vehicles exiting on Brunswick Road during an emergency evacuation.

The DEIR states that, "According to the Table 4.1 of the Circulation Element of the General Plan, Brunswick Road is considered a Minor Arterial, and thus, is not a primary evacuation route for the County." The DEIR neither addresses the safety plan for mine workers nor provides any mitigation if additional vehicles must use a minor arterial during an emergency evacuation.
Having to use a minor arterial for evacuations could result in a potentially significant emergency evacuation impact. The DEIR must be revised to provide a thorough analysis of these impacts. It must also fully mitigate for the Project's emergency evacuation impacts.

**The DEIR provides no details about the transport and storage of any other explosive materials besides Ammonium Nitrate, specifically detonators, explosive magazines, and detonating cords.**

**Grp 8-49** The DEIR states the mine will use 257 detonators a day. Table 4.7-1, "Explosives Proposed to be Used at Project" lists nine different types of detonators. However none of these are listed on the Hazardous Materials Inventory Statement Form and there is no information about how detonators or detonating cords would be stored. Nor does the DEIR provide information about how many and often these explosive materials would be transported through Grass Valley. Only ammonium nitrate is included in the 28,000 pounds of explosives shown on the "The Brunswick Industrial Site Nevada County Department of Environmental Health Hazardous Materials Inventory Statement Form" submitted by Rise Grass Valley.

Without this information, it is not possible to evaluate the environmental impacts associated with the transport and use of explosive materials. The revised DEIR must specify the transport and management of all explosive materials used in mining operations, in addition to Ammonium Nitrate.

**Curing of mass concrete can generate significant heat and needs to be managed.**

The project would dispose of 500 tons/day of sand tailings back into the mine by using Cement Paste Backfill (CPB). The quantities of cement to be used in this process are not specified in the Cemented Backfill Study written by the consultant Itasca that was submitted by the applicant. The DEIR should provide a range of expected cement usage as a basis for determining the impacts of the CPB process.

No analysis of heat generated by CPB is provided in the DEIR. For example, using a standard 6:1 ratio of tailings material to cement would require 83 tons of cement per day. The curing of cement (hydration) is an exothermic reaction with heat emissions exceeding 230kJ/kg, depending upon the cement Type. Using a conservative value, the heat from curing 83 tons of cement/day would add over 17 million KJ/day* to the environment. The revised DEIR must address the thermal impacts of CPB, including the following:

**Grp 8-50**

- How much cement would be used daily?
- How much heat would the curing cement produce? Over what area?
- What would be the maximum temperature of the curing CPB?
- Would it exceed 158 degrees F?
- What would be the resultant average and maximum temperatures in the backfill areas over time due to the daily additions of CPB and the resultant heat generated by the curing of the CPB?
- What heat management mitigations would be put in place to avoid undesirable rapid curing conditions which could create long term problems in terms of chemical stability, permeability, and strength?
- What mitigations would be established to protect workers from excessive heat?

**[Heat of curing is dependent upon the cement Type. Here, we use Portland Type IV: Heat 55cal/g ( note 1 cal/g == 4.184kJ/kg , 55cal/g * 4.184kJ/kg//cal/g == 230kJ/kg) (230kJ/kg x 907kg/ton == 208,610kJ/metric ton)*

**Dewatering hazards are not discussed.**

Upon initial dewatering, the physically sealed mine shafts such as the one under the Spring Hill Drive business will potentially experience a negative air pressure as the water level drops. The revised DEIR must address the structural impacts on existing infrastructure resulting from dewatering.

**Grp 8-51**

- How fast will the water level drop, and what volume of replacement air per hour would be necessary to equalize with atmospheric pressure within these sealed mine features?
- How will air enter the shafts as the water drops?
- How will this impact potential surface structures?
- Were the additional net load forces upon the sides and top of the shafts taken into consideration?

15

**The DEIR does not address potential riparian and surface water impacts from physical closure of the East Eureka Shaft.**

**Grp 8-52**

East Eureka Shaft and the East Eureka Drain are located under an existing building near Wolf Creek. Will work to physically close the Shaft precede the dewatering? If so, will construction be conducted underwater and/or below Wolf Creek top of bank?

When the water level in the mine workings is located near the ground surface, the drawdown of groundwater within the mine workings may increase the potential for settlement or collapse of shallow workings that were not formally closed. These issues are discussed in "DEIR Appendix H.6_Geotech Review of Near-Surface Features.pdf".

Potential impacts from dewatering could affect five mine shafts or mine features that are listed to be investigated and closed before dewatering begins: the East Eureka Shaft and the East Eureka Drain at 815 Idaho-Maryland Rd, the Idaho Drain Tunnel, the Idaho Pump Shaft, and the Idaho Shaft at 865 Idaho-Maryland Rd. These closures would affect businesses located above or near these mine features. The work at 815 Idaho-Maryland must take place under the Navo & Sons business building. The mine feature at 865 Idaho-Maryland Rd is in the middle of an operations yard.

**Grp 8-53**

The mine water levels at the five identified mine features are near the top grade and close to Wolf Creek. The DEIR fails to adequately describe the phasing of this repair work and does not disclose whether this work would impact water quality within Wolf Creek or its habitat. For example, in order to work on repairing, lining, and capping the East Eureka Shaft under the Navo & Sons building, either the work must be done underwater or the mine would have to be partially drained. Per DEIR Appendix H.6, "*The likely course of action will be to over-excavate surface soil in the areas of these features to determine where competent, native soil/rock is located and attempt to identify the trend of any subsurface mining-related structures (i.e. tunnel, shaft, drift, etc.).*"'

The mine water level is only slightly above Wolf Creek's normal flow levels and the mine drain is below the top of the bank. Some or all of the work is within the high water level of Wolf Creek. These conditions could result in environmental impacts but the DEIR provides too little information to understand the severity and extent of these impacts. The revised DEIR must provide the following information:

- Would the work be done before any dewatering of the mine and hence be underwater?
- Much of this work would be below the level of Wolf Creek. If work is done before partially dewatering the mine, how would concrete placement be achieved without interaction with the mine water discharge into the creek?

**Grp 8-54**

- If the work is done after partial dewatering of the mine, how would the risk of subsidence be mitigated, given that the repairs are prescribed to take place before dewatering in order to prevent subsidence.

**Grp 8-55**

- What are the required permits for work within a watercourse? None are listed.

**Grp 8-56**

A revised DEIR must specify how repair of the East Eureka Shaft (and the other near surface mine features listed) would proceed and include mitigation measures to protect Wolf Creek and the properties near to the proposed repairs.

16

## Hydrology

**Water quality related to cement backfill toxic discharge in mine water is not discussed.**

**Grp 8-57**

The project plans to dispose of 500 tons/day of sand tailings back into the mine using Cement Paste Backfill (CPB). The use of cement and CPB could have serious effects on water quality, yet the DEIR does not analyze these impacts. Long term potential effects from CPB and leaching must be analyzed. The DEIR fails to identify the quantities of cement, or ratio of cement to sand tailings and fails to evaluate the potential short term and long term impacts on water quality.

Cement can contain hexavalent chromium, which is a toxic and carcinogenic substance that has been known to leach from cement in concrete, causing groundwater pollution. Safeguards to prevent the use of cement containing hexavalent chromium must be provided. How will this be accomplished?

The DEIR must be revised to provide a comprehensive analysis of the environmental impacts associated with the use of cement and CPB.

**Assessments of the current mine water chemistry are inadequate.**

The Hydrology Report (DEIR Appendix K.2, Table 4-10, p120) uses discharge screening limits and data from the New Brunswick shaft to define water treatment criteria. However, a more accurate sampling of mine water would be from the drains located along Wolf Creek rather than from the New Brunswick shaft, as described in the analysis of mine water flow (see DEIR Figure 4.8-7), which shows water entering the New Brunswick shaft then flowing downward through the extant mineworks to exit the drains at Wolf Creek (Eureka drain, East Eureka drain, etc.). Only a few samples taken from the drains were reported, but these samples are much more representative of the mine water chemistry and indicate higher levels of Iron, Manganese, Arsenic, Aluminum, and Zinc than the New Brunswick shaft samples (DEIR K.2 Tables 3-6).

**Grp 8-58**

In order to get an accurate assessment of the contaminants flowing out of the mine under varying conditions, regular testing must be conducted over time at the Mine drains. The testing must also be conducted seasonally during differing rates of outflow. Moreover, in order to provide the public with a conservative estimate of potential impacts, the DEIR should use the results from the drain samples rather than the New Brunswick shaft, which would show potential water quality impacts from higher level of metals, arsenic and zinc.

Additionally, because the water flowing out of the drains probably only comes into contact with a small portion of the 72 miles of mine tunnels, current drain water does not likely represent the chemistry of the mine water that will be pumped out once dewatering begins. The DEIR should be revised to provide a comprehensive evaluation of the current mine's water chemistry. As part of this analysis, the following questions/issues must be addressed.

17

**Grp 8-59**

- Are there potential impacts from existing timbers and shoring on mine water quality?
- Were treated or rot resistant wood products used in the mine at any time?
- How has existing water quality been affected from the miles of pipelines, ore carts, rails, wiring, equipment, spilled oil products, chemicals and other miscellaneous materials which may have been left in the mine works?

**Grp 8-60**

A list of expected materials based upon historical records should be provided, and an assessment of risk, potential for contamination of the mine water, and a plan for their disposal provided.

- If detected, how will oil products be removed from mine water?
- If detected, how will Mercury and other contaminants be removed?
- Will the treatment facility have to be modified for any of the potential contaminants?

**Grp 8-61**

In previous operations up until the mine closed in 1956, a significant volume of mine waste or tailings was disposed of by backfilling the mine stopes. Water contained in backfilled stopes needs careful analysis due to potential leaching of contaminants when dewatering takes place. The amount of water is approximately 25 million cubic feet, or about half of the total mine water volume. This is a significant possible source of water contamination. The finely ground materials have been subject to oxidation already, they have been submerged for 75 years, and now would be subject to oxidation again as water levels drop, creating an increased potential for leaching of metals and metalloids. In addition, residues from ore processing such as mercury may be present. As the mine is dewatered, frequent regular testing of discharge must be done. The revised DEIR must provide the following information in order to evaluate the project's impacts:

- What plans are in place to test mine water as it is pumped out?
- How often will tests be conducted?
- What is the policy for ceasing or modification of pumping operations in the event of unexpected issues with water quality?

Additional analysis of the issues described above must be conducted to ensure an adequate understanding of these impacts which are potentially significant and unavoidable.

**Grp 8-62**

**Most of the samples that were tested to determine potential water quality impacts are unreliable.**

As detailed in "Sample QC Review", attached as a reference to this document, the environmental sampling data that was collected for determining potential water quality impacts fails to meet quality assurance standards, rendering the results unreliable. Most samples were received past hold times, and various samples were mishandled, mis-dated, submitted with temperatures exceeding the guidelines, and/or in too small a quantity to be measured. As a result, the consigned laboratories have denied certification of the data in several critical categories. In spite of this, the inadequate and often uncertified data was used in multiple consulting reports without any notation as to the validity of the compromised data.

For example all of the rock, tailings, soil, etc. samples that were used for the metals analyses were beyond their 6 months hold times, seemingly by at least 9 months, but records are inadequate. All 47

samples submitted to ACZ Laboratories were notated as "samples were received and analyzed past hold time." The bulk of the results were not offered for certification.

**Grp 8-63**

Findings regarding water quality, air quality, and hazards that are based upon this data are unreliable. Conclusions based upon this data must be reassessed based upon reliable sampling and analysis.

**Drill core testing for water quality impacts is inadequate.**

Given the size and scope of the proposed Project, there was an insufficient quantity of drill core rock analyzed to determine the mine's true impact on water quality.

By way of illustration, between 2017 and 2019, the applicant drilled for, and extracted, a total of 67,500 feet of rock core. But of these 67,500 feet of drill core, only 0.68% were submitted for analysis. And of the few samples that were submitted for analyses, a dearth of information is provided regarding the sample materials' true weight, volume, particle size, and sampling technique. Nor are the drill logs for these core samples available for review, so the actual dates, precise locations, drift angles, widths, final depths, etc. are unknown. Several times the DEIR refers the reader to a "separate report" which will explain some of these omissions, but no such report is found in the document or its appendices.

**Grp 8-64**

In addition to the limited sample size and the inadequate sampling details, four different labs were employed to carry out the analyses of the submitted samples, but the samples did not have a proper chain of custodies (COC) processes. The COC is a process that tracks the movement of samples through their collection, safeguarding, and analysis lifecycle between the mine applicant and the labs, but the COCs do not reflect the written account found in the DEIR.

The revised DEIR must provide an explanation for the discrepancies in the chains of custodies for the samples submitted to labs and provide evidence that the samples are scientifically reliable

This insufficient and unreliable data affects the accuracy of any analysis based on this data, such as an analysis of the metal leachate content of rock. Since metal leachate from mine rock affects water quality, analyzing metal leachate is one of the key concerns regarding the rock tailings produced by the Project. The limited amount of core material sampled and the imprecise manner in which the details of the core samples are reported makes the metal leachate analysis unreliable and leads the DEIR to underestimate potential impacts.

The revised DEIR should include a full set of data and drill logs that can be reliably analyzed by the public.

**Drill core testing for airborne contaminants is inadequate.**

**Grp 8-65**

As documented in "Sampling Procedures" (Sampling) (attached as a reference to this letter), TACs silica and asbestos are insufficiently described in the DEIR. Even though several hundred tons of rock would be mined and surface-stored each day, none of the core samples taken from the exploratory drill cores were tested for the contaminant silica. It also appears that when the original core samples were taken, drilling was stopped when serpentinite, an asbestos bearing rock, was encountered and, since drill logs are not available for review, the depth and width of the asbestos-containing serpentinite deposits encountered cannot be determined.

19

The rock types identified in the mineralized zone contain substantial amounts of silica (silicon dioxide, quartz), and the tailings would contain fine particles of respirable crystalline silica, a TAC. The laboratory that the applicant used for all metals analyses, ACZ Laboratories, is certified to perform both silica and silicon dioxide tests yet not a single sample was analyzed for these parameters (Sampling).

The revised DEIR should provide a full set of data about the samples analyzed for silica and asbestos. To the extent this data set fails to analyze silica and asbestos, further analysis and revisions of the DEIR are required to adequately identify impacts.

**The hydrology study incorrectly assesses the potential for long term acid mine type drainage.**

The Empire Mine, adjacent to the Idaho-Maryland Mine, provides clear evidence of the potential for contaminants that could be discharged from the Mine and from tailings and mine waste intended to be deposited on the surface or back within the Mine as backfill. Mine water discharged from the Empire Mine has excessive levels of arsenic, iron, and manganese.

The EMKO hydrology study used in the DEIR dismisses the potential for acid drainage which could affect water quality in Wolf Creek. Instead, the DEIR claims "Any acid generated during the oxidation would be quickly neutralized by the carbonate minerals in the host rock" and cites neutral or high (non acid) pH values. (DEIR 4.8-49, 50) However, the short term method used by EMKO is not a reliable method for predicting the long term potential for contaminants to be discharged from mine waste. Results would be more reliable using long term tests, on the order of months rather than hours or days.

**Grp 8-66**

The waste rock's potential to produce poor quality effluent should be thoroughly characterized using appropriate tests to the satisfaction of the Water Board (e.g., ASTM D 5744) over a sufficient period, also to the satisfaction of the Water Board (e.g., 40 weeks).

Accordingly, more extensive testing of mine waste rock and tailings must be conducted to assess the potential for contaminant leaching from mine waste. Long term dynamic testing must be conducted to accurately identify potential impacts to water quality. Due to variations in geology as mining progresses, repeated testing of the mine waste must be done.

The revised DEIR must specify how long-term monitoring of acid mine type drainage would be accomplished and identify mitigation measures capable of ensuring that any unanticipated contaminants do not adversely affect water quality. Without providing such testing and identifying feasible and effective mitigation measures, the impact must be identified as significant and unavoidable.

**It is not adequate to defer analysis of mine waste, a potential hazard, to some future date without providing substantial evidence that the proposed actions will not result in environmental impacts.**

**Grp 8-67**

The mine waste has not been adequately tested and one must conservatively conclude that it has a high potential for causing water quality impacts, given that similar local historic mining activities resulted in

20

the detrimental environmental impacts that persist today. The DEIR fails to conduct the necessary impact analysis. Instead the document asserts that impacts will be remedied by obtaining an expedited General Order permit from the Water Board (DEIR section 4.8 page 50). As Baseline points out, this process is insufficient:

*"It is not adequate to state that the project will get permits without providing substantial evidence that the proposed action will not result in environmental impacts, particularly when very similar historic actions have been demonstrated to result in environmental impacts that have persisted for decades."* (Baseline)

The revised DEIR must provide a valid and reliable analysis of the mine's waste products and identify specific and achievable mitigation measures to assure these water quality impacts are reduced to less than significant levels. Alternatively the revised DEIR must identify such impacts as significant and unavoidable.

---

**No provisions were made with respect to treatment of mine effluent beyond the 80 year project operations.**

Water treatment would need to continue in perpetuity after the mine stops. Current discharges have exceedances in Arsenic, Iron, and Manganese that would likely continue in perpetuity The DEIR must address potential water quality impacts and how water treatment would be accomplished after the mining operations cease.

**Grp 8-68**

The natural outflow is at Wolf Creek at an elevation of about 2650 feet elevation. Natural mine water level at Brunswick site is approximately 250 ft below the surface. Treating the water at the Brunswick site and discharging into SFWC requires at least a 250 foot lift.

- After mining operations cease what would be the provisions for long term treatment?
- What would be the long term energy demands?
- Where would the treatment facility be located after mining operations cease?
- What will be the biological and hydrological impacts from the changes in mine water discharge upon ceased operations?

In order to fully evaluate the Project's water impacts, these questions must be answered.

---

**Hydrology - Groundwater**

**The proposed project would intentionally affect local groundwater resources.**

**Grp 8-69**

The proposed Project would significantly affect local groundwater resources by dewatering the mine, lowering groundwater levels. The dewatered groundwater resources would be converted to surface water that is discharged into existing creek channels and quickly conveyed out of the area. The applicant's consultants have prepared a numerical groundwater model to attempt to predict how this proposed long term dewatering effort would affect overlying and surrounding groundwater levels.

21

An incorrect assumption was made in the groundwater model used to predict dewatering impacts, which led the DEIR to significantly underestimate groundwater drawdown, both in magnitude and areal extent. The groundwater model was calibrated based on pumping rates from the historical Idaho Brunswick Mine and only one water level measurement collected from the flooded (i.e., inactive) Union Hill shaft in 1956. Using only one water level measurement from 64 years ago to calibrate a complex bedrock aquifer system over a large region is inappropriate and introduces a significant amount of uncertainty to the model. (Baseline)

The revised DEIR must rely on a corrected groundwater model in order to accurately predict the extent of the well drawdown caused by the predicted 80 years of mine-dewatering and dewatered maintenance. Based on existing reports, the Project is likely to impact significantly more wells than the number of wells identified in the DEIR. (see "Safeguards for Well Owners and the Idaho-Maryland Mine", CEA Foundation) This is a significant impact that will affect hundreds of Grass Valley residents and must be addressed in a revised DEIR.

**The basic constructs of the DEIR's groundwater model have significant errors and omissions, making them unreliable.**

The basic data needed to build a valid groundwater hydrological model are missing. The document "Review of the Idaho-Maryland Mine DEIR Groundwater Model" (Model Review) by Silberstein examines deficiencies in the model, as summarized here.

**Grp 8-70**

The mine water drains from several locations along Wolf Creek near Centennial Drive, and the DEIR provides only rough approximations of the mine water outflow rates from these areas. What's more, these outflow data are contradicted by more reliable records from previous studies which indicate ten times more outflow than the amount the DEIR discloses. ( Model Review ) Similarly, mine water inflow analysis is based on sparse mine water level data from the New Brunswick shaft. Only 12 water level measurements were taken at random times of the year between 2003-2007, and just 3 measurements in 2018-19). In addition, the utility of these measurements is incorrectly interpreted. The water level reaches a limit when it exceeds the level of the drains from which the mine water flows and doesn't reflect what could be substantial inflow. Without a measurement of the outflow, the amount of inflow cannot be determined by the water level in the New Brunswick shaft. Essentially, no water balance assessment is provided.

Furthermore, data from private wells within the area is old and limited to just a few years. No usage data is provided, so seasonal variations in water levels are of limited use.

Critical data such as reduction in groundwater recharge from precipitation are also incorrectly calculated, failing to include the 75 acres of low-permeable mine waste to be dumped on the two sites.

Moreover, the groundwater model does not include the new access shaft, which would create a local area of groundwater drawdown. In fact, it appears that numerous existing mine features that are within a few hundred feet of the surface were also not evaluated in the ground water model. These mine features would contribute to the downward transmission of ground water from the near surface fractured rock areas.

22

These are all elements that are critical for constructing a reliable groundwater model to identify dewatering impacts.

**Grp 8-71**

In addition, there are three major faults and numerous minor faults in the mineral rights area. These impact the transmission of water and introduce a high level of uncertainty in the accuracy of a model which, as stated in the Groundwater Model report (DEIR Appendix K.3), assumes the geology is homogeneous. Common assumptions such as the correct anisotropic ratio for the groundwater transmission calculations may not be accurate.(Model Review, 3.g.)

Taken together, the groundwater model is seriously deficient with respect to data reliability, initial conditions, and modeling assumptions, calling into question its ability to accurately depict the Project's impacts.

**Grp 8-72**

Finally, use of modeling in a fractured rock system has limited value. Modeling that relies upon uniform rock, which is consistent from place to place, behaves in a more predictable fashion than rock that is in bedrock systems having multiple faults and irregularities. It is critical to provide for long term monitoring and extended protections due to the challenges inherent in modeling groundwater in this complex hydrogeologic setting.

The revised DEIR must provide accurate and adequate information and comprehensive analysis to determine the extent and the severity of the impacts upon groundwater resources and wells. Without this analysis, the revised DEIR must identify such impacts as significant and unavoidable.

**The DEIR inappropriately defers the collection of additional water monitoring data to the future.**

**Grp 8-73**

The DEIR acknowledges that more groundwater level data is needed to assess the potential impacts of the proposed Project on groundwater levels. Mitigation Measure 4.8-2(a)(4) (DEIR section 4.8 page 67) states that this needed water assessment be conducted "once dewatering of the underground mine workings commences." This is internally inconsistent and would not be achievable. Once dewatering begins, it will be impossible to measure baseline levels. Consequently, this mitigation measure is impossible to implement. Mitigation measures under CEQA must be achievable, enforceable, and must be capable of actually reducing the Project's impacts.

The DEIR inappropriately defers the collection of additional data (via a Groundwater Monitoring Plan) to the future. CEQA does not allow the deferral of important studies necessary to characterize impacts because it denies decision-makers the information they need to make well-reasoned decisions regarding the viability and impacts of a Project.

Groundwater monitoring networks will need to be established in advance of the Project, and the resulting data will need to be included in the revised DEIR. The consequences of not committing to full compliance with General Plan Policy 2.17 are dire for local property owners who rely on groundwater. (Baseline)

23

**Hydrology Modeling**

**Hydology Model Initial Condition Issues**

Dr. June Oberdorfer, Certified Hydrogeologist and Professional Geologist, reviewed the Ground Water Model and related hydrology documents for the Project. ( See "Comments on Itasca GW Modeling Oberdorfer.pdf", attached as a reference to this letter.) Several key assumptions were identified in the model which minimized the groundwater drawdown results. For example, an incorrect assumption was made for the initial water levels for the model. As described,

**Grp 8-74**

*"Rather than taking present day water levels as the starting point for predicting the effects of mining for 25 years starting in 2019, they chose to use the water levels at the end of mining in 1956 (Sec. 5.1). Those water levels don't reflect the fact that there's no current dewatering, but rather reflect dewatering at a rate of 700 gpm."*

As a result, Dr. Oberdorfer concludes:
*"This incorrect assumption minimizes both the magnitude of drawdown shown on the Figure 5-7 and the extent of the area affected. In addition to underestimating the number of domestic water supply wells impacted and requiring mitigation, this assumption also underestimates the extent of the area requiring groundwater monitoring (Itasca, 2020b). That area needs to be expanded."*

The revised DEIR must re-evaluate the area of potential groundwater impacts.

**Inflow and Transmissivity**

The groundwater model was created to simulate potential impacts to wells and groundwater levels. One of the key factors in modeling the groundwater is a determination of how readily water is transmitted from the surface into the mine. An analysis of water levels in the New Brunswick Shaft and possible correlations between precipitation was undertaken but it is flawed in several ways, further calling into question the basis for the groundwater model.

**Grp 8-75**

The analysis failed to consider that the level of the water in the New Brunswick Shaft had an upper limit because the water was flowing out of the drain, thus hiding potential increases in mine water inflow. Sparse data and poor granularity of data further undermine the utility of the New Brunswick Shaft water levels and corresponding precipitation amounts.

In addition, well monitoring was conducted in 1995-2001, 2003-07 (DEIR Appendix pg 4.8-11). Well log records show seasonal variability but no data is provided that shows how much of the well water level changes is due to irrigation season water usage and how much is a reflection of the actual lowering of the ground water level overall. No recent well monitoring was conducted during drought years, and no assessment was made on the long term predicted impacts of climate change. These impacts include warmer weather, changing rainfall amounts, shifting of rainfall periods, as well as consideration of water usage changes by property owners due to drought

24

The following minimal steps are necessary to accurately model the Project's groundwater impacts:

- Year-round logging of mine water levels and outflow should be collected. Data should be collected for several years, including at least one year with normal rainfall and one year each with low and high rainfall, in order to establish a baseline for groundwater modeling and impact assessment.

**Grp 8-76**

- The data from the outflow and the data showing changes in mine water level should then be compared with granular rainfall data to assess the amount of seasonal variation in mine water inflows. The data could then be used to provide an estimate of transmissivity from the surface.
- Adequate wells data should be collected. The wells data is old, limited to a few years, and lacks information about well water consumption. A comprehensive well monitoring program including water level and water comsumption must be established.

**Grp 8-77**

- If the mine is approved, monitoring must continue throughout mining operations and at least 5 years after the mine is closed and reflooded.

**Groundwater Model Elements**

A new access shaft is proposed close to the creek, but a cone of depression of groundwater levels like the one indicated at the New Brunswick Shaft is not shown in the DEIR. The failure to show this brings into question whether the new shaft is actually included in the DEIR groundwater model and subsequent analyses. The revised DEIR should provide the following information:

**Grp 8-78**

- Was the new access shaft included in the Itasca groundwater model? If so, what is its precise location? The shaft should be located on all maps.
- How far is it from South Fork Wolf Creek, a perennial stream? Is it within 100 ft?
- Was there analysis of the impact of the groundwater caused by the significant 50 ft deep excavation needed to build a permanent access shaft? If so, which specific pages of the DEIR provide this analysis?
- Will the new access shaft lead to more drawdown of near surface groundwater?
- How will the creation of a large excavation and a new access shaft impact the near surface ground waters that feed SFWC?

**Grp 8-79**

The model assumes that the areas to be mined will be confined to very limited areas at depths greater than 1000' (DEIR Appendix K.2, pg x, xi). However, the mineral rights provide no restriction to mining anywhere within the 2585 acres and to within 200' of the surface. No conditions are imposed to guarantee that the mine applicant doesn't drill, excavate, or mine above 1000 ft from the surface, which would invalidate the assumptions of the groundwater model.

**Grp 8-80**

The model simulations were constructed based on an assumption that mining would occur for only 25 years. From page 23 of "Appendix K.3_Groundwater Model Report" by Itasca: "The predictive numerical simulations were conducted to assess the potential inflows to the mine workings, the effect on nearby domestic wells, and the potential effects on the creeks in the Mine area during mine development and production between the assumed years of 2020 and 2045 (Year 1 to Year 25), which is the current mine plan." The model was subsequently extended to simulate an additional 40 years, providing a 65 year total run time. The model was not run for the full 80 year term of the proposed Project Use Permit.

25

All computer models that attempt to simulate real world conditions are based upon assumptions. Even minor differences between input data and actual real world conditions can result in errors that increase exponentially over time. The longer the computer model is run, the greater the potential for deviation from actual outcomes.

The DEIR should justify the additional run times of the groundwater model, along with an analysis of the reliability of the model over such an extended period of time.

All of these issues must be resolved in the revised DEIR.

**Wells and Well Mitigations**

**Relying on fifteen monitoring wells to estimate the impacts on all water supply wells around the mine area is inadequate.**

**Grp 8-81**

The DEIR relies on fifteen monitoring wells to estimate impacts on water supply wells but it does not explain how it arrived at this number of wells or their location. In complex fractured bedrock spread out over thousands of acres, monitoring water levels at fifteen locations could not possibly provide the needed data to ensure that groundwater impacts to hundreds of existing water supply wells in the Project vicinity are immediately identified and mitigated. (Baseline,p12)

The revised DEIR must provide reliable data regarding the Project's monitoring regime in order to provide an accurate accounting of groundwater impacts.

**Potential impacts to wells are underestimated and proposed mitigations are inadequate.**

The DEIR relies on a Well Mitigation Plan to allegedly protect wells from mining impacts. The Nevada County General Plan (Policy 17.12) item 1) states that:

"*In approving mining projects which* ***according to expert opinion*** *may threaten the existing quality or quantity of surface or subsurface water which supply adjacent homes and businesses:*

**Grp 8-82**

*1) The County shall require the operator to guarantee a comparable supply of water to such homes or businesses through accessible forms of security or alternate sources of water. "*

In contrast to the opinion of the DEIR consultant EMKO (DEIR Appendix K.9, p1), numerous experts have stated that there is the potential for a significant threat to water supply for wells in the area beyond those identified in the DEIR. Notably, Baseline Engineering unambiguously states that, "*...it is Baseline's expert opinion that the project may threaten the existing quality or quantity of surface or subsurface water which supply adjacent homes and businesses in a much wider area than is indicated in the DEIR.*" (Baseline)

The DEIR relies on a Well Mitigation Plan to purportedly protect wells from potential mining impacts. Yet, the Well Monitoring Plan does not demonstrate that impacts would be mitigated. The Well Mitigation Plan is an aspect of the DEIR which designates protections for wells from potential mining impacts. The Nevada County General Plan states that if expert opinion indicates that there may be a

threat to the quality or quantity of water that supplies domestic wells, then the mine operator must provided an immediate and comparable supply of water, and will be held accountable for all expenses incurred unless the operator can prove that they are not at fault.

The Well Mitigation Plan asserts that, "*Expert opinion has determined that there is no threat to water quality to domestic water wells...*" and that, "*Domestic wells outside [the E. Bennett Road] area will not be impacted.*"

By stating such, the mine applicant is downplaying the Project's impacts on area wells so that he can avoid having to comply with most of the County's Well Mitigation requirements.

Outside experts have determined that the DEIR's hydrology model is unreliable because there were so few well-monitoring measurements collected and because the quantity of data-input was insufficient to calibrate any reliable conclusion. As one expert noted,

"*Even a well-calibrated model has a large uncertainty in its predictions. It turns out that this model [Rise'] is not well calibrated, so the uncertainties are almost certainly larger [than the norm].*"

**Grp 8-82**

Six of the experts who have assessed the potential threat to local wells from mining activity repeatedly emphasized the uncertainty of the predictability of the mine's impact to domestic wells.

Given the opinion of outside experts, it is imperative that well owners both within and beyond the area of mineral rights owned by the mine applicant be guaranteed an equivalent, uninterrupted, permanent, quality of water, supplied and paid for by the company in advance of any mining operations.

The DEIR must be revised to provide an adequate analysis of impacts to wells. Once this analysis is provided, the applicant and the County will be in a better position to identify feasible and effective mitigation for these impacts. As a first step, the revised DEIR must accurately define the area of potential impact to domestic wells. The revised analysis must provide the quality and quantity of data needed so that the hydrological model can calibrate a more reliable prediction of threat. The data collected must cover all the seasons (over an extended period of time), and include a large enough quantity of representative wells - over a long enough period of time – to establish a baseline usage of the wells in all the neighborhoods whose wells could be threatened by mining activities. The monitoring should be managed by a qualified and independent third party.

Then a fair and accurate domestic well monitoring program must be designed and implemented. This well monitoring program must include full financial assurances covering all well owners in the area that addresses bonding, warranties for NID services, damage reimbursements, etc. Additionally, a community relations program should be established to handle any problems that might emerge over the eighty year permit being requested.

**Hydrology - Surface waters**

**Grp 8-83**

**Mine water discharge will overheat the South Fork Wolf Creek.**

Mine water temperature ranges between 14 and 15 degrees Celsius. The Project must not change the temperature of water discharged into the South Fork Wolf Creek by more than 5 degrees Fahrenheit (2.8C) per NPDES requirements. ( DEIR Appendix K.2, p108) Water from the mine will be pumped into the seven acre treatment pond. From there it will be run through the treatment facility and discharged into the creek. The DEIR's Hydrology study provides only a few data points (April and August of 2019 and Jan 2020) to determine the range of values for the creek flow and temperature, reporting lows of 9 deg F in the winter to 15 deg F in late summer (DEIR Appendix K.2, pg 108).

However, over 15 years of monitoring by (WCCA) provides data indicating that the temperature of the creek often falls substantially below 10C, and that these temperatures commonly occur during low flow times.

The revised DEIR must include studies that reliably predict the mine water's outflow temperatures from the treatment pond into SFWC. To do this, the EIR must include thermal modeling of the treatment pond, including the temperature impacts due to the treatment processing plant, flow through rates, cooling under different weather conditions, solar gain, evaporation, precipitation, etc. In order to avoid impacts to the SFWC and the species that inhabit the Creek, the revised DEIR must demonstrate that the discharge temperature and flow rates, combined with the temperature and flow rates of the stream over a range of conditions would not result in temperature changes in the stream in excess of 2.8C (5F) degrees.

**Grp 8-84**

The Hydrology report states that:
"*During the winter and early spring, the temperature of the water in the mine would be more than 2.8 degrees C warmer than the creek. However, after being pumped from the mine, the water would be stored within a surface pond before treatment and discharge. During the winter and early spring,* ***the ambient temperature should cool the water in the pond****. In addition, the rate of discharge would be less than the typical flow rates in South Fork Wolf Creek during the winter and early spring, such that the discharge* ***should not alter the temperature in the creek by more than 2.8 degrees C****. Therefore, the discharge would comply with the temperature criteria in the NPDES permit.*" (DEIR Appendix K.2, pg 108)

The section of the Hydrology report addressing creek temperatures is speculative because it is based on incomplete data. It is not sufficient to say "the ambient temperature should cool the water" and "the discharge should not alter the temperature of the creek by more than 2.8 degrees C." Advisory language such as this does nothing to ensure that resources will be protected.

**Grp 8-85**

The low flow periods of the stream in the fall and early winter often have low temperatures and would be potentially the worst case for temperature impacts due to mixing. This is not adequately assessed in the DEIR. The revised DEIR must address the following:

- What are the predicted high and low temperatures of the discharge from the treatment pond in all seasons of the year, and considering varying weather conditions?
- Which specific temperature scenarios were considered in the DEIR?
- What are the corresponding flow rates of the stream and what would be the resultant temperature change of the mixed waters?

28

**Grp 8-86**

To accurately predict the outflow temperatures, the revised DEIR must conduct thermal modeling of the treatment pond, including the temperature impacts due to the treatment processing plant, flow through rates, cooling under different weather conditions, solar gain, evaporation, precipitation, etc. The document must then undertake calculations to demonstrate that the discharge temperature and flow rates, combined with the temperature and flow rates of the stream over a range of conditions would not result in temperature changes in the stream in excess of 5 degrees F.

**Hydrology - Surface Waters**

**Impacts from using the 7 acre freshwater pond for treating minewater are not adequately assessed.**

**Grp 8-87**

The 7 acre pond will be filled with untreated mine water. The outflow of the pond is to South Fork Wolf Creek. It has been modified to increase capacity. Currently it provides habitat for abundant waterfowl and is surrounded by riparian vegetation.

The proposed treatment process will cause Iron and Manganese to precipitate via oxidation in the pond. These oxides will accumulate. Also Arsenic and other contaminants will accumulate. Concentrations of contaminants will exceed the contaminant levels from the discharged mine water due to additional oxidation, mine water recirculation, evaporation, and treatment plant residues from backflushing. What is currently a healthy freshwater pond with good water quality and abundant wildlife will become contaminated. The revised DEIR must address these impacts:

- What will be the impact of the contaminated water on waterfowl and surrounding riparian habitat?
- What mitigation will be provided to replace the habitat and to protect wildlife from exposure to the contaminated water?

**Grp 8-88**

- Water for mining operations will be recirculated into the mine. How will the concentrations of contaminants in the pond be monitored to prevent addition of metal to the mine waste stream?
- Will mine workers be protected from exposure? How?

**Grp 8-89**

- Will water be tested to assure it will not increase the risk of future groundwater contamination when it is used in the cement paste backfill?

**Grp 8-90**

- What impacts will the contaminated mine water have when used for dust suppression and Asbestos management?

**Grp 8-91**

- Aeration of water in the treatment pond can cause odors and toxic substances to become airborne. What are the air quality impacts?

**Grp 8-92**

There will also be potential leaching of contaminants from mine waste that will be exported as engineered fill or sold offsite. Untreated water that may be used to control fugitive dust emissions and/or increase water content in "engineered fill" may increase those contaminants. The revised DEIR must address the following:

- What safeguards will be used to prevent additional contaminants present in the untreated water from increasing the total levels of contaminants present in the exported materials?
- How often will the water used on exported materials be tested?

29

- In the event that the total level of contaminants in material destined for export exceeds the thresholds for toxic contaminants, how will the material be managed? Where will it be placed?

**Periodic removal of treatment pond precipitants.**

Grp 8-93

The treatment pond would be used to remove some or all of the Iron, Manganese, and other contaminants in the mine water by oxidation. Periodically, the pond must be drained and the accumulated precipitants must be removed. There are number of impacts from this process that are unaddressed in the DEIR:

What are the impacts on the surface waters from draining the 40 acre foot treatment pond?
How will the dewatering maintenance process be managed during this operation?
Will testing be conducted on the precipitants?
How will the precipitants be classified, and where will they be taken?

These impacts must be addressed in the revised DEIR.

## Land Use, Zoning, Population and Housing

**A variance for proximity to geological faults is not supported.**

Industrial development must be located at least 200 feet from any fault line. The DEIR fails to provide a map showing the location of all of the faults and the 200 foot setbacks along with the locations of the proposed industrial buildings. A drawing showing these relative locations is necessary in order to evaluate the potential impacts of the fault (See map, DEIR Appendix H.2, Figure 1 and 2).

Grp 8-94

There seems to be an attempt to obfuscate the issue of variances by noting the location of the existing New Brunswick Shaft within the 200 foot setback. As an existing structure, a variance for use of it as a secondary access to the mine is a lessor potential impact than a variance for proposed new industrial buildings.

Pg 5 states: "Because the proposed Project includes development of industrial facilities associated with underground mining operations utilizing the New Brunswick shaft, construction within the building setback fault zone is necessary and unavoidable. There is no alternatively feasible location that would have less impact on the Site and surrounding areas."

This statement is not valid. First, the site of the historic Idaho-Maryland Mine main access and processing facilities was at the Centennial site on Idaho-Maryland Road. This would be a suitable site for the industrial facilities. In fact, it is a more suitable due to the nature of adjacent land use and fewer impacted residential properties. To further support this point, note that in 2008 Emgold Mining Corp. submitted an application to open the mine at the Centennial site, including all of the processing facilities. The Brunswick site and the Round Hole site were to be for additional access, ventilation and emergency access. Having multiple access points from different parts of the mine works also provides better emergency access and ventilation. The current proposal by Rise Gold has all of the access to the

entire mine works located at two shafts within a short distance of each other, which lacks those benefits.

Thus, the statement that "There is no alternatively feasible location that would have less impact on the Site and surrounding areas…" has not been established as valid. At the very least, evidence should be provided supporting this claim.

**Grp 8-95** Furthermore, as noted in FaultingHazards, the impacts of mining will change the mass balances on either side of the faults with the potential to induce seismic activity.

**Grp 8-96** This variance should be denied.

**Alternative Land Uses are not adequately discussed.**

**Grp 8-97** The DEIR Alternatives chapter discusses only an alternative use that would result in an industrial project on the Brunswick site at maximum buildout potential. It is then dismissed for evaluation because impacts were concluded to be greater than the mine project. This is a severe inadequacy in the DEIR.

In order to adequately address project alternatives, the DEIR must discuss an alternative use that would be more likely at this site - such as a project consistent with the site zoning, not requiring a use permit, and of a scale which is designed to avoid significant mine project impacts. An alternative industrial use appropriately scaled at this site would be more likely to meet the community character and aesthetic related policies in the General Plan and result in reduced impacts compared to the mine project in virtually every impact area including visual, traffic, air quality, and noise/vibration.

**Grp 8-98** The DEIR is also deficient in not mentioning or analyzing the mine project's inconsistencies with the Grass Valley General Plan. The mine project is within the Grass Valley Sphere of Influence. The Centennial site is within Grass Valley's first phase annexation area. A portion of the Centennial site is also zoned by Grass Valley for Urban Medium Density housing. The Nevada County General Plan requires the county to designate lands within the cities' Spheres of Influence consistent with the city land use designations. The county has not done this; thus the Industrial designation and the mine project's operations are clearly inconsistent with its own General Plan and the Grass Valley General Plan. Physical land use compatibility impacts (industrial uses next to medium density housing) will also result. In addition, the DEIR should evaluate the City's and the County's General Plan land use policy text and zoning texts for consistency. These are potentially significant impacts which must be discussed in the DEIR.

**Grp 8-99** The revised DEIR must also determine whether the dumping of mine waste is a heavy industrial activity.

**Grp 8-100** **Maps and Plans**

The Brunswick site shows a 100 ft building setback and an NID spill easement on an open creek, South Fork Wolf Creek. The map also shows a fault line. The map is dated 1987. Apparently this perennial stream was buried in a culvert since 1987, based upon the map's date.

- Was the burial of SFWC done under an authorized permit?
- What is the status of the NID spill easement?
- Have the 100 ft setback and NID spill easement been waived or reconveyed to the land owner?

Any existing easements or setbacks which may be encroached by the Project must be waived or modified by the consent of the entitled party.

**Grp 8-101**

What is presumably the Weimar fault, also known as the 6-3 Fault, (See https://www.risegoldcorp.com/uploads/content/I-M_Tech_Report.pdf ) runs through the project site, although, surprisingly, the DEIR does not actually refer to it by name. The site map showing the Fault Line and Setback Zone ( DEIR Appendix H.2, Figure 1) for this is inadequate. None of the proposed structures for the Project are shown.

**Grp 8-102**

A map with South Idaho Shaft precisely located and with the Pine Hill flannelbush locations shown must be provided to safeguard inadvertent intrusion into the flannelbush protection areas

**Grp 8-103**

A map showing the mineral rights zone and all the parcels identified by address must be provided to adequately inform the public regarding the location of residences and businesses in the area with respect to the mine.

## Noise and Vibration

**Nighttime noise impact is not adequately addressed.**

**Grp 8-104**

The analysis "Acoustical Comments on Draft Environmental Impact Report, Salter Project 22-0039" (Salter) provides comments on the DEIR's analysis of the noise and vibrations for the Project.

Salter determined that nighttime noise is not adequately addressed in the DEIR. The DEIR outright dismisses the potential for noise impacts due to sleep disturbance and inappropriately excludes this consideration from the DEIR analysis. The combination of nighttime industrial activities amongst a community that currently enjoys low ambient noise levels represents a significant risk for Project noise to impact the community, annoy residents, and cause sleep disturbance.

A revised DEIR should provide a comprehensive analysis of nighttime noise impacts, identify these as potentially significant impacts, and identify appropriate mitigation, including limitations on nighttime noise, to protect nearby residents (Salter).

**Engineered fill operation noise is underestimated.**

**Grp 8-105**

The DEIR underestimates operational noise from the Project's engineered fill operations (Impact 4.10-2). This 5 to 6-year long activity could generate noise levels at least 10 to 18 dB higher than predicted in the DEIR. This is a significant deficiency in the impact analysis. As such, the project's noise levels could be 20 to 35 dB louder than current median/background ambient noise levels, causing a severe

32

impact. In addition, in several instances, the DEIR fails to adequately address impacts to sensitive receptors located farther away from existing roadways that currently have a lower background noise (Salter).

These are potentially significant impacts. The DEIR must be revised to correct these deficiencies and omissions.

**Blasting vibration impact is not adequately addressed.**

**Grp 8-106**

The DEIR fails to adequately evaluate blasting vibration impacts (see Impact 4.10-4). Blasting operations have the potential to subject nearby residents to "strongly perceptible" and borderline "unpleasant" vibration on a regular basis for the rest of their lives. These perceptible and unpleasant vibrations must be considered a significant impact in the DEIR.

In particular, the DEIR fails to include crucial guidance from the U.S. Office of Surface Mining Reclamation and Enforcement Blasting Guidance Manual restricting blasting vibration during evening and nighttime hours. If blasting must be allowed at these sensitive times, the DEIR must incorporate adequate mitigation with a notably stricter limit at all sensitive receptors (Salter).

**Stoping and the new access shaft construction requires noise and vibrations analysis.**

**Grp 8-107**

In addition to the vibrations of the blasts, the DEIR fails to analyze impacts associated with long hole slope blasting, i.e. the landing impact shock from long hole stope rock falling. Long hole slope blasting has the potential to create significant shock waves.

**Grp 8-108**

The DEIR fails to evaluate the vibrations from the rock falls during the construction of the new access shaft. The top 60 feet of the shaft will be built from above by excavating and forming a concrete structure. The remainder of the shaft will be excavated by tunneling from below. The analysis of the construction noise for this shaft did not include blasting from below, and shock waves from that near surface blasting, and the shock waves when volumes of rock drop vertically up to 1000 feet.

**Grp 8-109**

The shaft excavation which is proposed to be constructed from below cannot begin until the mine has been dewatered to over 1000 feet and mine works have been restored from the New Brunswick shaft entrance to the location of the bottom of the new access shaft. In light of this information, the revised DEIR must answer the following questions:

- What is the total time that the new access shaft will be under construction?
- How long after the initiation of the site construction will this new access shaft excavation phase begin?
- How long after the initial dewatering of the Mine will the construction of the new access shaft begin?

**Grp 8-110**

The DEIR's Appendix M_Blasting Report.pdf recommends that "...IMM hire a blast consultant to assist with the development of a 95% confidence level equation for the site-specific ground vibration. This consultant would take the data acquired by the seismographs set-up on the mine, run a linear regression and log-log confidence model to develop an equation that the mine can use to modify blasting, as needed, to ensure vibration levels remain at acceptable levels." (DEIR 7.2, p28)

33

In order to mitigate the risks of vibration impacts, this must be a requirement, not a recommendation. In addition, in order to protect the public from vibration impacts, the revised DEIR must add as a requirement or a condition of approval that the applicant cease operations if vibrations are in excess of 0.5 in/sec. Absent these additions, the impact must be considered significant and unavoidable.

## Other Issues

**The DEIR has not demonstrated that mine waste disposal by off site sales would be viable.**

**Grp 8-111**

The DEIR indicates that the applicant (Rise) plans to sell waste rock on the open market if it is still being produced after the two proposed waste rock piles reach capacity (DEIR Project Description). The Regional Water Board has jurisdiction over the disposal location requirements for mine waste rock. Although the DEIR does not disclose this, the concept of selling waste rock is an unrealistic and infeasible proposal unless the Water Board has determined that such discharges would not pose a threat to water quality. Accordingly, the Project should not rely on this concept and the DEIR should identify all impacts associated with alternative disposal methods.

Even if the mine waste can be sold, the market for aggregates varies significantly by season. During rainy seasons, it may be necessary to stockpile the aggregate onsite, but there are no provisions for onsite storage in the DEIR or an assessment of impacts related to such storage. As reported by the Center for Science in Public Participation (CSP2), dispersing waste rock and other mine waste over large areas without containment often results in contamination (e.g., Calcine mercury mine tailings used for road construction in San Luis Obispo County).

**Grp 8-112**

The absence of provisions for temporary waste rock storage (and the associated analysis of its impact) creates strict operational constraints and potentially significant impacts on all phases of processing have not been addressed in the DEIR. The DEIR should be revised to include an analysis of these impacts.

**Construction time estimates are inadequate and affect noise, traffic, air, and other impact areas.**

Construction time estimates in the DEIR are contradictory and inadequate. For example, the DEIR states in several instances that the Project is estimated to have a twelve month construction phase, but also states that the construction of the water treatment facility alone would take eighteen months.

**Grp 8-113**

Furthermore, neither of these estimates - twelve or eighteen months - is sufficient to capture all phases of construction. As just one example, the applicant would have to complete significant grading and underground development before initiating the eighteen month construction of the water treatment facility. Similarly, the water treatment facility would have to be completed before dewatering of the mine could begin. Dewatering is a six month process. After dewatering has been completed, the new shaft for ventilation and emergency access would have to be constructed to the 1000' depth by working upwards from below. Then, before beginning any actual new mining, the tunnels would need to be restored sufficiently to allow for construction of the underground rock crushing facility. All of these activities must happen sequentially, not in parallel. Therefore, a more reasonable estimate of

34

construction length for the Project would be four to six years, clearly resulting in significantly different annual and cumulative impacts than the ones identified in the DEIR.

The DEIR should be revised to provide an accurate description of each construction project, including its intended duration. This revised description must also include the sequencing of construction projects. Until this information is provided, the DEIR preparers will be unable to properly assess the annual and cumulative impacts on air, noise, traffic, aesthetics, and other resource areas.

## Permits

Grp 8-114 Construction phase repairs to the 7 acre pond on the Brunswick site will require draining the pond, repairing the pond berm, and lining the pond with a membrane. Impacts to surface waters and the wet meadow below the pond must be assessed.

Grp 8-115 The Project includes a 165' tall headframe which requires a height variance. Several other buildings are over the county limit for building height as well. Consideration should be given for putting a substantial portion of those structures underground to reduce the visual impacts and mitigate the excessive height.

## Conclusion

Grp 8-116 As documented throughout this letter, the DEIR lacks critical information necessary to identify all potentially significant impacts associated with a large underground mining project close to a populated area. The Adocument lacks he DEIR lacks an accurate project description, relies on an incomplete baseline for evaluating the project's environmental impacts, lacks data and analyses needed to make informed determinations, underestimates or omits impacts and fails to provide effective and feasible mitigation measures. For these reasons, the document is inadequate under CEQA. The DEIR must be revised accordingly and recirculated.

**Concerns:**

**Grp 8-127**

Simulations by Itasca (2020a) of the effects of mine-dewatering produced a map of predicted drawdowns after 25 years of dewatering (Figure 5-7). The contours of equal groundwater drawdown in this figure show a maximum drawdown of approximately ten feet and the extent of drawdown over one foot approximate the limits of Rise Gold's mineral rights. This figure was reproduced by EMKO (2020a) and served as the basis for determining which private wells would experience excessive drawdown and thus need to be mitigated with a supplemental water supply from the Nevada Irrigation District.

An incorrect assumption was made in the running of these future predictions of mining impacts which led to a significant underestimation of groundwater drawdown, both in magnitude and areal extent. This assumption needs to be corrected to get both a more accurate prediction of the extent of the well drawdown caused by the predicted 25 years of mine-dewatering and a more accurate determination of the number of wells needing to be mitigated with supplemental water supply.

The computer model was calibrated to match historic dewatering rates (700 gallons per minute [gpm] toward the end of historic mining in 1956) and one groundwater measurement taken from near the end of the historic mining period at the Union Hill Mine shaft (a small mine that had been inactive for many decades). These calibrations are reflected in Figure 4-7 (Itasca, 2020a). The lower part of this figure shows a hydrograph (water elevation versus time) for simulated water levels within the New Brunswick Mine for the 700-gpm dewatering rate. Simulated water levels in the mine were around 1,150 feet above mean sea level (ft amsl) at the end of historic mining and recovered rapidly to about 2,500 ft amsl after the cessation of mine-dewatering.

The top portion of Figure 4-7 (Itasca, 2020a) shows a hydrograph of the calibration to the historic water level measurement in the Union Hill Mine shaft at the end of mine-dewatering when the water level was approximately 20 feet lower than at present. In order to calibrate to this

one historic water level, Itasca had to insert a very low permeability barrier next to the Union Hill Mine into the model to create sufficient hydraulic isolation of the Union Hill Mine from the much lower water levels in the adjacent area. The hydraulic isolation of this Union Hill Mine area is supported by the fact that the current water levels in its shaft are about 165 feet higher than water levels in the New Brunswick Mine.

What is not known, other than at this one point in the Union Hill Mine, are the shallow groundwater levels in 1956. Itasca (2020a) does not present a map of groundwater drawdown for 1956 (as they do for the predictive modeling of 25 years into the future). Those simulated water levels in 1956 would provide important insights into what future water levels during mine dewatering would be and should be presented.

The water level in the Union Hill Mine shaft is shallow, and it is quite likely that the drawdown in 1956 in the shallow groundwater to the west (in the vicinity of the New Brunswick Mine) was significantly greater than the 20 feet observed at the Union Hill Mine, probably on the order of or greater than the 165-foot water level difference observed at present. Water levels to the west could have been on the order of 185 feet or more lower than present (20 feet plus 165 feet). It is a major shortcoming of Itasca's modeling report that they do not provide a drawdown map or hydrographs of the effects of historic mine-dewatering on the shallow aquifer.

**Grp 8-128**

The incorrect assumption that was made in the predictive modeling of future 25 years of mine-dewatering was in the initial condition (starting water levels) for that predictive simulation. Rather than taking present day water levels as the starting point for predicting the effects of mining for 25 years starting in 2019, they chose to use the water levels at the end of mining in 1956 (Sec. 5.1). Those water levels don't reflect the fact that there's no current dewatering, but rather reflect dewatering at a rate of 700 gpm. The incremental drawdown from increasing dewatering from 700 gpm to the future rate of 900 gpm is what is reflected in the map of impact (Figure 5-7, Itasca, 2020a) used to determine the area requiring mitigation by Rise Gold. Examining the predicted drawdown in Figure 5-7 in the vicinity of the Union Hill Mine, it would be expected to be greater than the historic drawdown measured of 20 feet if dewatering has increased over the historic rate. With drawdown being proportional to pumping rate, the drawdown would be expected to be on the order of 25 feet in the vicinity of the Union Hill Mine. Instead, drawdown in this area is on the order of a few feet (Fig. 5-7). Drawdowns further to the west in the vicinity of the New Brunswick Mine should be considerably greater than 20 feet, which they are not. This reduced drawdown compared to what was observed historically is the result of the incorrect assumption for the initial condition for predictive modeling.

**Grp 8-129**

This incorrect assumption minimizes both the magnitude of drawdown shown on the Figure 5-7 and the extent of the area affected. In addition to underestimating the number of domestic water supply wells impacted and requiring mitigation, this assumption also underestimates the extent of the area requiring groundwater monitoring (Itasca, 2020b). That area needs to be expanded. If the effects on dewatering on the discharge to nearby streams were calculated similarly to the effects on groundwater drawdown, then the amount of decrease in groundwater discharge to adjacent streams could be underestimated as well.

**Grp 8-130**

Itasca should clarify the results of their simulations by producing:

1) Both a groundwater drawdown contour map and a groundwater elevation contour map for the shallow aquifer immediately before the cessation of dewatering in 1956.

**Grp 8-131**

2) Hydrographs for simulated heads in the shallow aquifer for the historic period 1920 to 2020 plus continuation for the 25 years of predictive modeling for future mining. The hydrographs should be for groundwater elevation in ft amsl versus time for the 125 years and represent the heads in the shallow aquifer near wells labeled WS95, WS216, WS201, WS80, WS 91, and WS85 on Itasca Figure 2-6.

**Grp 8-132**

3) Model water budget (all volumetric water inputs and outputs) for the general area of the mineral rights boundary over the 125 years simulated, preferably in plot rather than tabular format, using the one-month time increment used in the modeling.

**Grp 8-133**

4) The model should be run using the 2019 water levels as the initial conditions for the predictive simulations. Contour maps, hydrographs, and water budgets should be provided for these revised predictive runs.

SAMPLE QUALITY CONTROL REVIEW

The EPA Hazardous Waste Test Methods SW-846 Compendium establishes guidelines for sampling and analyses such as sampling containers, preservation and recommended hold times for analytes.

Recommended holding times ensure that the sample is analyzed for the requested parameter prior to any bio-degradation, oxidation, precipitation, sorption, volatilization, and other physical and chemical processes that may occur that can affect the integrity of the sample.

All metals were digested using EPA Method 3050B. The results should be defined as the "Total acid soluble/recoverable metals" fraction since this method does not use hydrofluoric acid, thus it is unable to break down silicates. (EPA SW-846 Revision VI December 2018, Chapter 3, pg 4)

**Grp 8-134**

Chapter 3 of the SW-846 Revision VI December 2018, pp 21-22 has the following footnotes regarding preservation and hold times:

a These recommendations are intended as guidance only. The selection of sample and digestion volumes/mass and preservation and holding times should be made based on the nature of the sample, the intended end use of the data and the data quality objectives.

1 The exact sample extract, and standard storage temperature should be based on project-specific requirements and/or manufacturer's recommendations for standards. Alternative temperatures may be appropriate based on demonstrated analyte stability within a matrix, provided the data quality objectives for a specific project are still attainable.

2 A longer holding time may be appropriate if it can be demonstrated that the reported analyte concentrations are not adversely affected by preservation, storage and analyses performed outside the recommended holding times.

SEE ATTACHED FILE: SW846 Metals

And while these guidelines are only "recommended" by the EPA, the context of data usage must be considered. The metals analyses data are being used in toxic metals leachate analyses and toxic air contaminant emissions. Also, heavy metals concentrations are known to potentiate the effects of asbestos toxicity. Since **the intended end use of the data** directly impacts public health, data quality is of utmost importance.

1

**Grp 8-135**

The recommended EPA holding times have been missed in both aqueous and solid sample categories.

SOLIDS-HOLD TIMES

Pages 515-516 of the *Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO shows a list of 47 samples that were sent out for "gold determinations" to ALS Laboratories in Reno, NV (pg. 93, *Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO). These samples are listed as from drill cores I-18-02*, I-18-10, I-18-11, I-18-12 and I-19-13. DATE RECEIVED is noted as 02-20-2019.

*NOTE*: In Table 4-9 Barren Rock Crushed Core Sample Trace Metals Results (*Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO Pg 101)
The sample listed as I-18-02 in the Appendices (pg 515) is now labelled B-18-02. Sample depths of 948- 958 bgs correlate between I-18-02 and B-18-02 labelled samples.

This means that all of the rock, tailings, soil, etc. samples that were used for the metals analyses were beyond the 6 months hold time. How far beyond that window is currently unknown since exact sample dates for the individual drill cores are not available-but this date (02.20.2019) suggests expiration by at least 9 months. Where are the drill logs needed for confirmation?

ACZ Laboratories lists the sample dates as 03.05.2019 for all 47 "soil" samples for metals analyses. The laboratory received by date for all samples is 11.11.2019. Again, the samples may have been collected for shipment on 03.05.2019 but their actual sample dates were months prior.

Twenty samples were digested on 11.22.2019 and the remaining twenty-seven samples were digested on 11.26.2019. (The digestion dates would be used for endpoint hold time calculations). All data is notated that the "samples were received and analyzed past hold time". (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO Inorganic Extended Qualifier Reports pp. 389-407 and 458-484, Appendix D)

The samples MA-1, MA-2, MA-3, MAA-1, MS-1 and S-1 were collected by Benchmark Resources on 10.29.2019 for the leachate studies. Samples "collected" were from I-18-10, I-18-11 and I-19-13 drill cores. (*Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO Pg 93)

ACZ Laboratories lists 10.29.2019 as the sample date for this study when again these samples were obtained prior to 02.20.2019. (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO pp 495-500)

Mercury analysis has a 28-day hold time and requires storage between 0-6°C (pg. 316 Sample Receipt form states that the cooler temperature was 18.8 °C, criteria ≤ 6.0. Wet or gel ice not present). These results are notated "Sample was received above recommended temperature" and "Sample matrix is solid rock and a homogenous sample aliquot could not be created for Hg analysis prior to preparation and air drying. Hg analysis was performed on crushed, homogenized, and air dried (40C) sub sample. Some loss of Hg may have occurred. Residual moisture on the prepped sample fraction was used for data collection."

Sample Receipt form states: "Some parameters were received past hold time" when in fact, ALL PARAMETERS WERE RECEIVED PAST HOLD TIME.

In addition, sample L55806-02 (MA-2) was noted "sample container was broken, was placed in ziplock bag". The type of sample containers was not provided on any COC forms. If these samples were stored in glass, then all boron analyses are invalid since it may be leached from glass containers.

2

Some general chemistry parameters (Chloride-WET DI, Nitrate/Nitrite as N -WET DI, Nitrate as N-WET DI, Sulfate)-WET DI are notated: "Analysis is outside the intended scope of the method, which does not provide hold time information for soil extracts. No hold time is observed for collection to extraction. The referenced method hold time is observed for extraction-to-analysis". The Nitrate/Nitrite as N-WET DI and Nitrate as N-WET DI were also notated as "Sample was received above recommended temperature" and the Nitrate as N-WET DI had the additional notation of "Sample was received and analyzed past holding time". (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO pp 297-314)

On page, ACZ Laboratories states that "The following parameters are not offered for certification or are not covered by NELAC certificate #ACZ": Boron (WET DI), Solids (Percent), and Sulfate (WET DI)". ((*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO pp. 315,355 Certification Qualifiers)

ACZ Laboratories lists 10.29.2019 as the sample date for M-1, M-2, M-3, MAA-1, MS-1 and S-1 along with sample date of 11.04.2019 for F-1, F-2, F-3 and F-4 on the Acid-Base Accounting tests when again these samples were obtained prior to 02.20.2019 (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO pp 501-504). F1-F4 samples are a composite of core tailings that were drilled prior to 02.20.2019. For some reason, these samples were not received by ACZ Laboratories until 01.29.2020.

On pp 510, (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO), Certification Qualifiers have the following statements:

"The following parameters are not offered for certification or are not covered by NELAC certification #ACZ:

- Neutralization Potential as CCO3 M600/2-78-054 NV Modified Sobek Procedure
- pH, Saturated Paste EPA 600-2-78-054 section 3.2.2
- Sulfur HCl Extractable M600-2-78-054 3.2.4 & 3.2.6 NV Modified Sobek Procedure
- Sulfur HNO3 Extractable M600-2-78-054 3.2.4 & 3.2.6 NV Modified Sobek Procedure
- Sulfur Hot H2O Extractable M600-2-78-054 3.2.4 & 3.2.6 NV Modified Sobek Procedure
- Sulfur Residual M600-2-78-054 3.2.4 & 3.2.6 NV Modified Sobek Procedure
- Sulfur Total M600-2-78-054 3.2.4 & 3.2.6 NV Modified Sobek Procedure

These were the methods used for Acid-Base Potential determinations.

AQUEOUS SAMPLES

All coliform tests (E. coli, Fecal and Total) exceeded hold times (pg. 99, *Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*).

All pH tests exceeded hold times since this is a field test to be performed within 15 minutes.

**Grp 8-136**

D-1 sampled on 02.13.2018 exceeded hold times for BOD, MBAS, $NO_3$ and $NO_2$.

ED-1 sampled 02.13.2018 exceeded hold times for BOD, MBAS, $NO_3$ AND $NO_2$.

The data is notated as such in the Appendices, pp 83-89.

All samples in the Fish Bioassay study were notated:
"12/21/18 Only 1 10 Liter effluent sample was provided for the initiation and renewal therefore could only perform a 25% renewal on day 2." (*Appendices: Groundwater Hydrology and Water Quality Analysis Report for The Idaho-Maryland Mine Project*, EMKO pp 222-228)

3

**Grp 8-137**

Both Ben Mossman and Andrew Kopania received copies of all laboratory reports. The cover letter from ACZ states that: "This report shall be used or copied in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report."

However, the data from these analyses is used in multiple consulting reports without any notations as to the validity of the data.

Thank you,

SW-846 Update VI THREE - 20 Revision 6 December 2018

## GROUP LETTER 8: RALPH SILBERSTEIN, COMMUNITY ENVIRONMENTAL ADVOCATES FOUNDATION

### Response to Comment Grp 8-1

This comment is introductory in nature, states that the DEIR is inadequate, but does not provide any specific comments on the DEIR. The commenter's specific comments are addressed below in Responses to Comments Grp 8-2 through Grp 8-137. In addition, responses to the referenced Baseline comments are provided in Responses to Comments Grp 21-107 to Grp 21-128; and responses to the referenced Salter comments are provided in Responses to Comments Grp 21-129 to Grp 21-145.

### Response to Comment Grp 8-2

The commenter asserts that the images of the facilities provided in the DEIR are not a fair representation of the actual visual character of the project, which causes the DEIR to understate visual impacts. As discussed in Section 3.2 of Appendix D to the DEIR, photographs from each viewpoint were taken from approximately 5½ feet above ground level, the approximate eye level of an average standing human. The camera lens was adjusted to mimic the perspective of the human eye (approximately 55 millimeters). Panorama photographs were taken to include peripheral elements that a viewer would see and present the view of the project site in relation to the surrounding area or viewshed.

The DEIR has already determined the project's aesthetic impacts to be a significant and unavoidable. Therefore, further analysis with the different photography method suggested by the commentor would not impact the significance determination set forth in the DEIR.

### Response to Comment Grp 8-3

The commenter states that the use of an erosion control seed mixture for reclamation of the engineered fill piles would cause a "dead zone" and implies that this will cause an aesthetic impact. The commenter then states that native vegetation including deciduous and evergreen bushes and trees should be required as mitigation. The engineered fill piles require use of an erosion control seed mixture to prevent erosion of the slopes due to precipitation. While native plants may start to naturally grow on the slopes after reclamation, use of evergreen bushes is not an adequate method to prevent erosion; therefore, the erosion control seed mixture is the preferred reclamation method. The commenter's suggested mitigation would lead to significant erosion impacts and is therefore not appropriate for the project. Furthermore, the forestation of slopes on engineered fill piles was examined as an alternative in Section 6 of the DEIR and, as discussed on page 6-15 of the DEIR, while the planting of trees along the slopes of the Centennial and Brunswick engineered fill piles would reduce the proposed project's aesthetic effects by adding screening, the substantial slopes would not be fully screened due to the required tree spacing, and the aesthetic impact would be anticipated to remain significant and unavoidable. Therefore, this alternative would not be anticipated to avoid or substantially lessen a significant impact identified for the project. Given the limited efficacy of this alternative, it was rejected from further consideration.

### Response to Comment Grp 8-4

Please see response to referenced Baseline comment. Please see Response to Comment Grp 21-124.

## Response to Comment Grp 8-5

The Brunswick site is not located in the Loma Rica Drive Industrial area and therefore not subject to the Loma Rica Drive Industrial Area Plan. The referenced language refers to FAA regulations governing buildings, radio towers and other structures that physically obstruct aircraft flight paths due to their height. The project does not propose any structures that would be tall enough to be considered an obstruction under FAA regulations in the applicable airport safety zone. The project will be reviewed by the Airport Land Use Commission as it would have a building floor area of 20,000 square feet or greater, would include more than 100 people on-site, and would include new development of buildings more than 100 feet tall in Zones D and E. (DEIR, p. 4.7-36.) However, airspace review is not required for the project because the tallest point of the project (the 165ft headframe) would be at 2,912 feet msl, while the threshold for airspace review is almost 300 feet higher at 3,207 feet msl. (DEIR, p. 4.7-36.) The commenter does not explain how mine exhaust would be considered an "object" subject to these regulations.

The project would not create a persistent cloud plume or fog, and the commenter provides no substantial evidence to support its claim that the mine exhaust would create turbulence. This comment is speculative, and CEQA does not require that an EIR analyze speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." Please see Response to Comment Grp 7-95 regarding mine exhaust moisture.

## Response to Comment Grp 8-6

The commenter asserts that the mine exhaust could cause persistent fog and turbulence. However, the project would not create a persistent cloud plume or fog, or cause turbulence. Please see Response to Comment Grp 7-95.

## Response to Comment Grp 8-7

Please see Response to Comment Grp 7-95 regarding mine exhaust moisture.

## Response to Comment Grp 8-8

Please see Responses to Comments Grp 7-95 and Grp 8-5.

## Response to Comment Grp 8-9

The commenter summarizes comments from Group Letter 7. Exploration and testing for asbestos is conducted before mining of materials. The DEIR includes asbestos testing requirements and mitigation measures to ensure asbestos exposure to the public and workers will be less than significant. Please see Responses to Comments Grp 7-6, Grp 7-7, and responses to the referenced ASUR Plan Analysis in Grp 7-103 through Grp 7-137. Please also refer to Master Response 22 - Conservatism of Asbestos Assumptions.

## Response to Comment Grp 8-10

The commenter summarizes comments from Group Letter 7. No such stockpile is proposed for the project. Please see Responses to Comments Grp 7-6, Grp 7-7, and Grp 7-137.

## Response to Comment Grp 8-11

The commenter summarizes comments from Group Letter 7. No such stockpile is proposed for the project. Please see Responses to Comments Grp 7-6, Grp 7-7, and Grp 7-137.

## Response to Comment Grp 8-12

The commenter summarizes comments from Group Letter 7. No such stockpile is proposed for the project. Please see Responses to Comments Grp 7-6, Grp 7-7, and Grp 7-137.

## Response to Comment Grp 8-13

The commenter states that asbestos and silica are toxic air contaminants with no identified safe exposure levels, and that the HRA should analyze 80 years of exposure. Further, the commenter states that the DEIR needs to identify clear and achievable mitigation measures with robust monitoring systems of waste rock during transport and disposal.

As stated on page 4.3-42 of the DEIR, the NSAQMD's cancer and noncancer thresholds to assess health risk significance of asbestos and silica exposure for CEQA are consistent with what are used for the AB 2588 risk assessment procedures. The threshold of significance for health risk is an increased cancer risk of >10 cases per million persons. The Health Risk Assessment prepared for the project concludes that the health risk to the most sensitive receptor, including silica and asbestos exposure, will be below this threshold. The Health Risk Assessment is based on conservative assumptions. Please see Master Response 22 – Conservatism of Asbestos Assumptions and Master Response 21 – Conservatism of Silica Assumptions.

While the commenter requests that the HRA analyze an exposure timeframe of 80 years, OEHHA recommends that a 30-year exposure duration be used as the basis for estimating cancer risk at the maximum exposed individual resident (MEIR) in the Hot Spots Program. This exposure duration represents the time of residency for 90 to 95% of Californians at a single location and should provide adequate public health protection against individual risk. (Section 8.1 OEHHA 2015 Air Toxics Hot Spots Program Manual).

Nevertheless, the DEIR concludes that the project could result in a significant impact with respect to exposing receptors to substantial concentrations of asbestos and requires mitigation to reduce the impact to a less than significant level. Mitigation Measure 4.3-2 of the DEIR requires the submission of an Asbestos Dust Mitigation Plan (ADMP) to Northern Sierra Air Quality Management District (NSAQMD) for review and approval. The ADMP has minimum requirements as described in the mitigation measure. Additional measures, such as air monitoring if required by the NSAQMD, would be detailed in the ADMP. The NSAQMD may revise the ADMP on the basis of air monitoring.

## Response to Comment Grp 8-14

The commenter states that the use of Blue Canyon's meteorological data for the HRA is not valid and that the DEIR must use different data for its analysis. The dispersion model in the Health Risk Assessment used the most appropriate data for the HRA. Please see Master Response 17 - Meteorological Data Used in HRA.

## Response to Comment Grp 8-15

The commenter asserts that the DEIR needs to analyze the impact of the project on radon levels, including data on existing background radon levels of all homes and properties near the project. Elevated radon gas levels in indoor air are a result of radon moving into buildings from the soil, either by diffusion or flow due to air pressure differences. The ultimate source of radon gas in buildings is the uranium naturally present in the rock, water, and soil. Some rocks types are known to contain more uranium than others. However, geology cannot be used to predict whether a

particular building will have a radon problem. (CDHS 1991).[1] Radon can also enter homes through their water systems when using domestic wells. The areas most likely to have problems with radon in groundwater are areas that have high levels of uranium in the underlying rocks. (USGS 1992).[2] According to maps prepared by the California Department of Health Services, there are no known rock formations with elevated uranium in western Nevada County (see figures 2-4, 10-13 of CDHS 1991). There are granitic rocks in Nevada County, which may have elevated uranium; however, there are no granitic rocks in the mineral claims area (see Sheet 4 of Appendix K.2).

Moreover, underground mining would not affect radon entry into buildings because the vibration levels are much lower than would be required to damage the foundation or structure (see Section 4.10-4 of the EIR). Radon levels in homes along E. Bennett Road who choose to use NID water may have reduced radon in their homes as water from groundwater wells can contribute to radon levels in indoor air. As such, the project may reduce existing radon levels, if any radon exists, in the 30 parcels proposed for connection to NID water. Because the mining activities will only lead to the drawdown of groundwater and thus not provide recharge to the domestic wells, the mining activities at the project site should not affect the water quality of the domestic wells. (Page 14 of Appendix K.8). Any naturally occurring radon currently in groundwater would be unchanged by the project.

Radon is not considered a toxic air contaminant by the OEHHA or CARB and does not have an associated reference exposure level. Further, the commenter provides no evidence that the project could cause impacts related to radon exposure, and simply speculates that impacts may result. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." As this comment amounts to speculation, no analysis of radon related impacts is required.

## Response to Comment Grp 8-16

The commenter asserts that the DEIR failed to analyze impacts relating to South Fork Wolf Creek, including benthic macro-invertebrates, trout and other aquatic species. The commenter further states that the DEIR fails to analyze impacts to "an entire reach of South Fork Wolf Creek." However, DEIR Chapter 4.4 and Chapter 4.8 analyzed potential project impacts to biological resources and hydrology and water quality affecting South Fork Wolf Creek, respectively, including the portion of the creek that the commenter claims was excluded. As outlined in Section 4.4.1 (Introduction) and included as Appendix F, eleven different technical studies were prepared documenting existing environmental conditions and analyzing potential biological impacts from the proposed project. This includes a specific biological assessment technical report analyzing treated project water discharge to South Fork Wolf Creek (see Appendix F.10). These technical reports were prepared by biologists with over 30 years of local expertise in the species and environment within the project site. These technical studies were then peer reviewed by the County and its independent environmental consultants. The peer review of biology reports was conducted by a biological firm with similar local experience that resulted in several rounds of review and revision prior to the County's acceptance of these reports for use in the DEIR. As a

[1] CDHS (California Department of Health Services. 1991. *Geologic Controls on the Distribution of Radon in California.* California. Available at: https://www.conservation.ca.gov/cgs/Documents/Melange/Geo_Controls_Dist_Radon.pdf.

[2] USGS (US Geological Survey. 1992. *The Geology of Radon.* United States. Available at: https://pubs.usgs.gov/gip/7000018/report.pdf.

result, numerous biological experts with local knowledge have analyzed and reviewed the characterization and analysis included in these biological technical reports prior to their use and incorporation into the DEIR. In addition, as summarized in Chapter 4.8, and included in appendix H and K, ten different technical reports and peer reviews related to hydrology and water quality were prepared documenting or confirming ground and surface water conditions at the site and potential impacts from the proposed project. Specifically, two technical reports (Appendix K.1 and K.2) analyzed treated water discharge from the project and its potential impact to South Wolf Creek. These technical documents were also peer reviewed by the County and their environmental consultant.

Special status species that may utilize South Wolf Creek were analyzed in Impact 4.4-2 including Foothill Yellow-Legged Frog (FYLF) and Western Pond Turtle. Analysis of the Olive-sided flycatcher, Willow flycatcher, Yellow-breasted chat, and Yellow warbler has been added to Section 4.4 in the Final EIR. No significant impacts to these species were identified. As discussed in Impact 4.4-2, VES method surveys were conducted for FYLF along South Fork Wolf Creek within the project site and portions that flow through public property within Empire Mine State Historic Park. FYLF were not identified during these surveys. Impact 4.4-2 summarizes site and hydrologic conditions in South Wolf Creek within the project site and offsite demonstrating marginal habitat for FYLF. In addition, Impact 4.4-2 addressed potential treated mine water discharge impacts to FYLF and benthic macroinvertebrates and concluded this impact would not be adverse. As explained in Impact 4.4-2, and detailed in Chapter 4.8 and Appendix K.1, the proposed project will discharge a maximum of 5.6 cubic feet per second (cfs) of treated mine water to South Fork Wolf Creek. Base flow in South Fork Wolf Creek may range from 0.17 cfs in the summer to 6.5 cfs in the winter between storm events. Sediment pebble count analysis (see Appendix K.1) indicates that the flow rate at which sediment within the channel may become mobilized ranges from 20 cfs to 90 cfs. With the addition of the maximum proposed discharge of 5.6 cfs and increasing measured baseflows by a 50 percent safety factor, post-project baseflows during nonstorm periods would be expected to range between approximately 5.8 cfs and 15 cfs. These estimates are less than 23 cfs, the threshold for bedload sediment mobility and well below flows that commonly exhibit significant work on the channel (with minimal bed sediment becoming mobilized and minimal or no bank erosion, bed scour, or channel avulsion). The DEIR therefore concludes potential downstream impacts to the stream channel and associated riparian zone along both sides of South Fork Wolf Creek from the additional discharge of 5.6 cfs would be minimal on sensitive biological resources, such as foothill yellow-legged frog, and do not represent a potential significant impact to the stream channel or associated riparian zone within South Fork Wolf Creek. Additionally, peak flows on the South Fork Wolf Creek are expected to be lower than pre-project conditions due to the stormwater detention basin being constructed on the project site as part of the project. Please see Master Response 33 - Groundwater Dependent Vegetation; Master Response 32 - Temperature of Mine Water Discharge; Master Response 34 - Resident Fish; Master Response 35 - Discharge to South Fork Wolf Creek; Master Response 36 - Flows in South Fork Wolf Creek and Wolf Creek; Master Response 37 - Birds and Raptors; and Master Response 38 - Foothill Yellow Legged Frog and California Red Legged Frog.

## Response to Comment Grp 8-17

Regarding the comments pertaining to the rate treated water discharge into the South Fork Wolf Creek, please see Response to Comment Grp 7-32. Regarding the assertion that the DEIR does not consider seasonality of streamflow, loss of streambed or streambank habitat, differences in Specific Conductance, and habitat for BMI, please see Responses to Comments Grp 7-34 and Grp 31-35, as well as Master Response 36 - Flows in South Fork Wolf Creek; and Master Response 35 - Discharge to South Fork Wolf Creek.

Regarding concerns related to changes in water temperature, please see Response to Comment Grp 7-36 and Master Response 32 – Temperature of Mine Water Discharge.

Regarding drawdown of water table and impacts to various habitats, please see Master Response 33 – Groundwater Dependant Vegetation.

Regarding concerns regarding cumulative impacts to BMI, trout, and other aquatic species, please see Response to Comment Grp 7-35.

## Response to Comment Grp 8-18

The commenter asserts that the DEIR failed to analyze impacts from preparation of the Centennial Site for the cleanup project and subsequent use for placement of engineered fill. Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA.

## Response to Comment Grp 8-19

The Centennial Biological Resources Assessment (Appendix F.2) and Centennial Impact Technical Memorandum (Appendix F.3) used the Brunswick site as the reference location for the 5-mile radius CNDDB report and figure. Updated CNDDB 5-mile radius figure has been provide below using both the Brunswick and Centennial Industrial Site as the reference location. As shown in these figures, no new species were identified that have a moderate or high potential to exist onsite. With respect to yellow-breasted chat shown on the figures, please see Master Response 37 – Birds and Raptors.

## Response to Comment Grp 8-20

Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA. In addition, please see Section 1.3 of the DEIR for a full explanation of the baseline approaches used for the project.

## Response to Comment Grp 8-21

The commenter states that approval of the Draft RAP is uncertain; therefore, the DEIR must use a baseline of existing conditions for the Centennial Site. The commenter's suggested baseline would be misleading, because the project could not place any material on the Centennial Site until after the DTSC cleanup project is completed and in the case that the DTSC project did not proceed, the project would proceed without any use of, or impact on the Centennial Site. Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA. In addition, please refer to Section 1.3 of the DEIR for a full explanation of the baseline approaches used for the project.

## Response to Comment Grp 8-22

Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA. In addition, please see Section 1.3 of the DEIR for a full explanation of the baseline approaches used for the project.

## Response to Comment Grp 8-23

Soil storage locations are shown on Sheets 3 and 5 of the Reclamation Plan (Appendix C of the EIR). The movement of soil is included and accounted for in the air quality impact analysis.

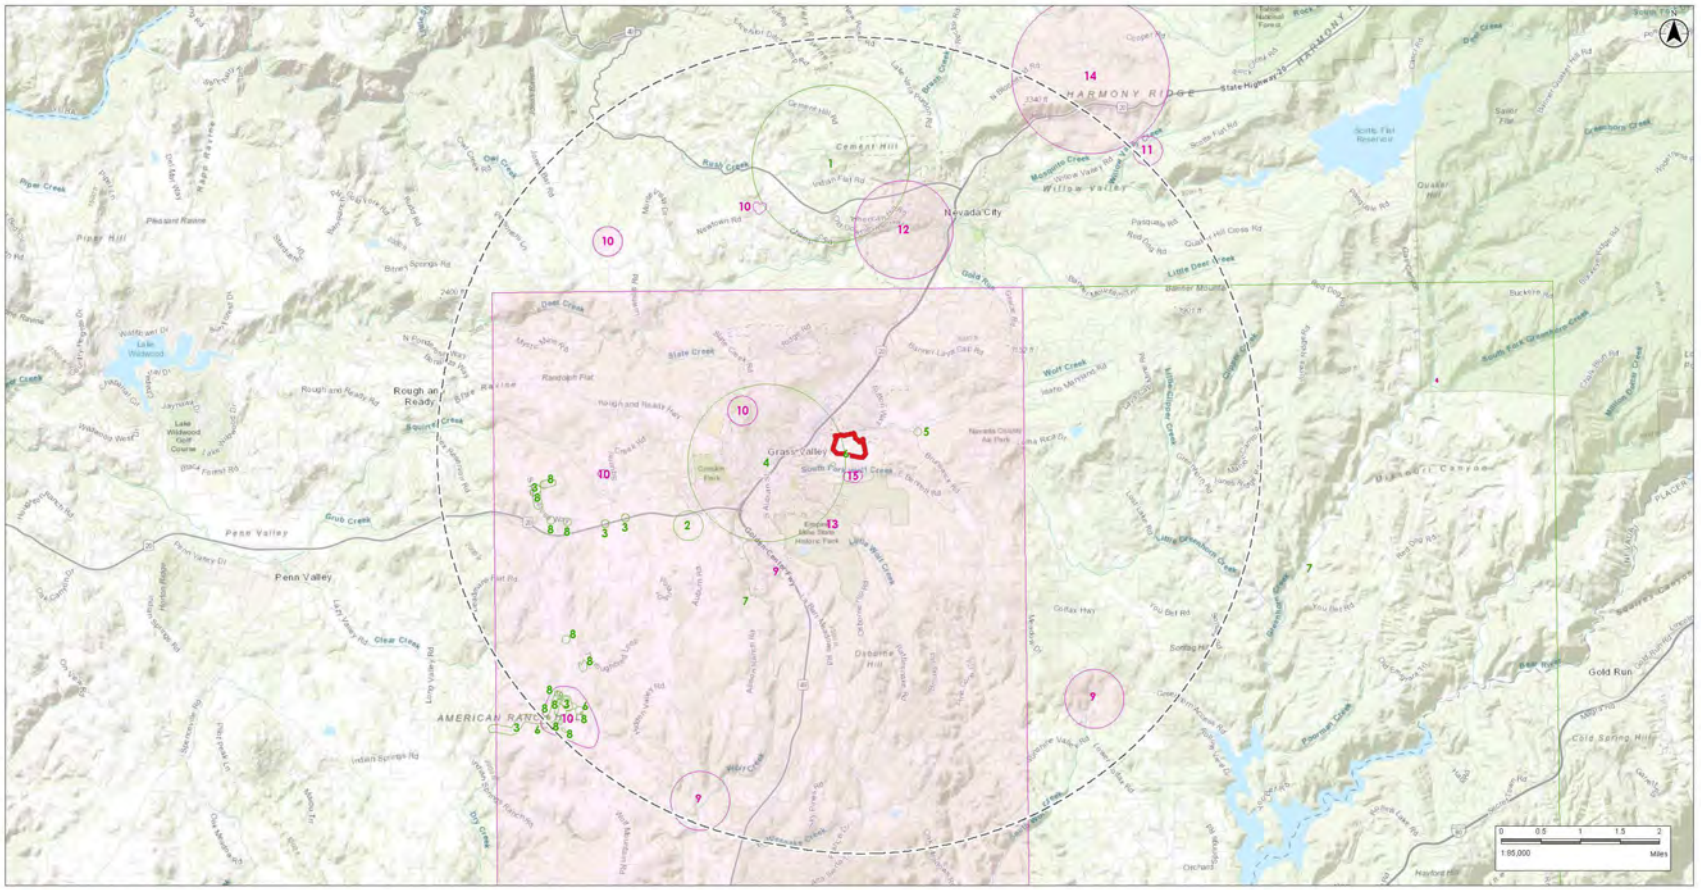

**Figure 3. CNDDB and Critical Habitat Map**

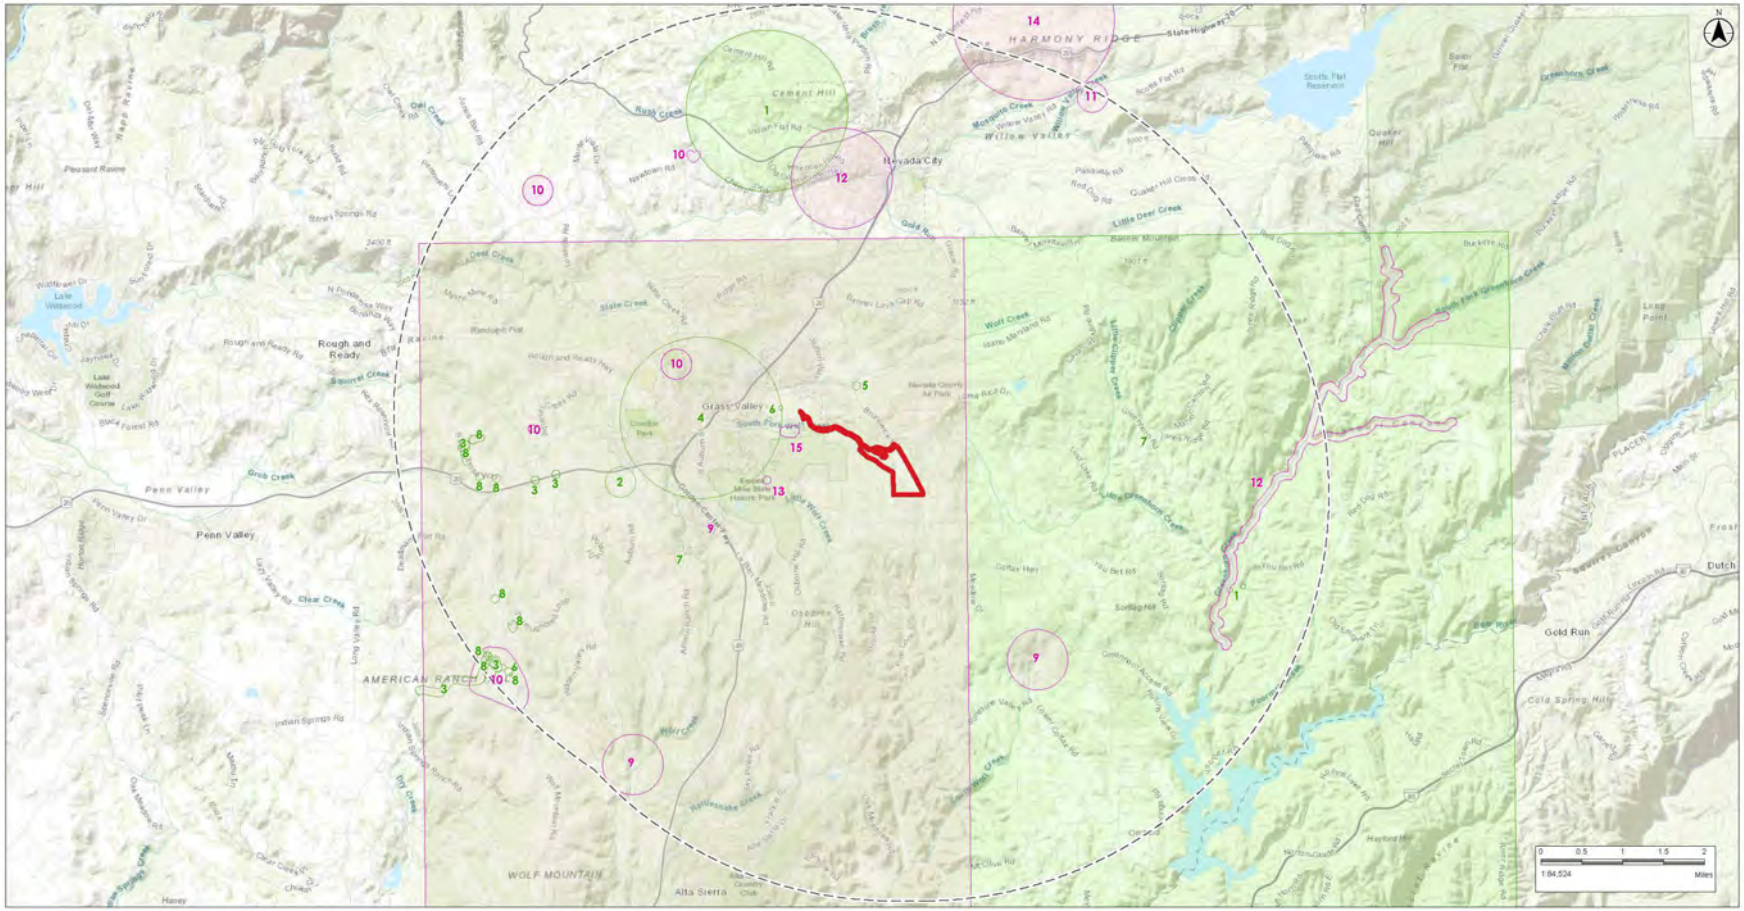

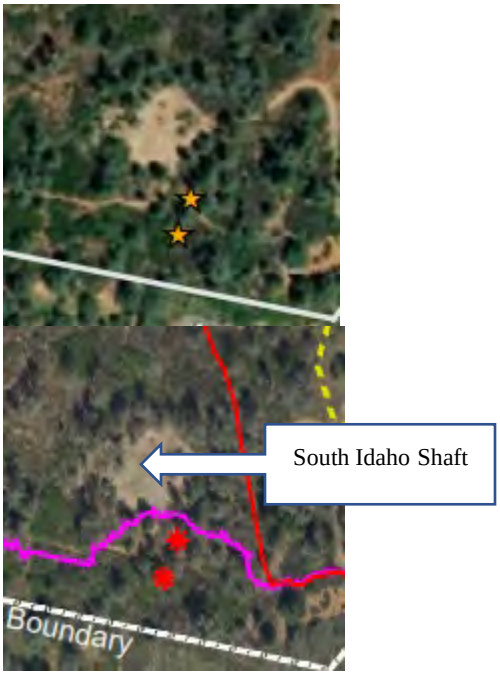

**Figure 3. CNDDB and Critical Habitat Map**

## Response to Comment Grp 8-24

The South Idaho Shaft is inside the area of proposed placement of engineered fill at the Centennial site. Impacts to flannelbush plants have therefore already been analyzed in the DEIR. The location of the South Idaho Shaft is shown as a distinctive circular opening on the southeast portion of the Centennial Site on the Figure in Appendix D of Appendix F.4 of the DEIR. The South Idaho Shaft is outside of the DTSC cleanup disturbance area and inside of the Idaho-Maryland Mine Project disturbance area as shown in Figure B of Appendix F.4 of the DEIR. No flannelbush plants are located in the location of the South Idaho Shaft as can be seen on these figures.

Clips of figures referenced above from Appendix F.4 are shown below for clarity of the response.

## Response to Comment Grp 8-25

Appendix F.3 and Appendix F.4 were technical reports prepared by an independent biologist with analysis of potential impacts and recommendations for protection measures. The County peer reviewed these documents, and as appropriate, incorporated the analysis and recommendations into the DEIR. The DEIR, which includes mitigation measures where appropriate, uses the terms "shall" or must" and therefore are enforceable. (See Mitigation Measure 4.4-1(a).) For example, Mitigation Measure 4.4-1(a) states "Prior to issuance of grading permits, the applicant shall record a Conservation Easement for the on-site Pine Hill flannelbush avoidance area, or use a similar land protection mechanism that runs with the land in perpetuity, to protect the Pine Hill flannelbush plants within the avoidance area." (Emphasis added.)

## Response to Comment Grp 8-26

The commenter states that the DEIR's Habitat Management Plan (HMP) for Pine Hill flannelbush proposes to remove 18 plants and that 4 other plants could be impacted, but does not explain why the plants need to be removed. The commenter requests that the DEIR be amended to eliminate the need to remove the 18 plants. As explained in DEIR Impact 4.4-1:

> "The proposed placement of engineered fill at the Centennial Site would impact 18 Pine Hill flannelbush plants directly by requiring their removal as part of the Idaho-Maryland Mine Project. The remaining 42 individual Pine Hill flannelbush plants are located outside of the proposed engineered fill areas and therefore, they would not be directly impacted by the Idaho-Maryland Mine Project. However, four individual Pine Hill flannelbush plants would be located within 30 feet of the edge of the engineered fill material and could be subject to indirect effects from changes in topography, runoff, etc. that could occur as an edge effect on those individual plants."

As discussed above, the need to remove the 18 plants for placement of engineered fill and possible impact to 4 other plants due to the proximity to the engineered fill pile was already discussed in the DEIR in Impact 4.4-1. Further, as demonstrated above, impacts to Pine Hill flannelbush were addressed and considered potentially significant. A mitigation measure was identified requiring the preparation and implementation of a habitat management plan (see Mitigation Measure 4.4-1(a)) reducing this impact to a less than significant level.

## Response to Comment Grp 8-27

Appendix F.4, Habitat Management Plan for the Pine Hill flannelbush, section 6.3 explains the transplantation and monitoring timing requirements for impacted Pine Hill flannelbush. The location of transplantation will be similar soil, hydrologic, vegetation type and aspect.

As explained in Appendix F.4, a maintenance and monitoring program is identified for transplanted Pine Hill flannellbush. Monitoring will occur every six months for the first two years. If transplantation does not meet success criteria, monitoring and maintenance will continue until those success criteria are achieved (see Appendix F.4, section 6.3.2). Irrigation is not prevented and could be utilized if determined necessary to ensure the success of transplantation. The monitoring and maintenance will continue until success criteria are achieved. If those success criteria cannot be achieved, Mitigation Measure 4.4-1(a)(5) and the draft management plan provides alternative maintenance transplantation measures to help achieve success criteria.

The commenter asks for detailed site activity phasing but CEQA does not require engineering level details. (*Dry Creek Citizens Coalition v. County of Tulare* (1999) 70 Cal.App.4th 20, 26.).

## Response to Comment Grp 8-28

Please see Responses to Comments Grp 8-24 to Grp 8-27. The commenter does not provide environmental reasons why the conclusions of the DEIR are incorrect, and rather concludes that impacts are significant and unavoidable. The DEIR, specifically Impact 4.4-1 and Appendix F.4, provide substantial evidence the potential impacts to Pine Hill flannelbush have been appropriately analyzed and provides mitigation reducing the impact to a less than significant level. Further, the project's Pine Hill flannelbush impacts and the DEIR's proposed mitigation have been peer reviewed by the County's independent biologist.

## Response to Comment Grp 8-29

Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA. In addition, please see Section 1.3 of the DEIR for a full explanation of the baseline approaches used for the project.

## Response to Comment Grp 8-30

Please see Master Response 4 – Cleanup Project is a Separate Project under CEQA. Please see Response to Comment Grp 7-78 regarding impacts to recharge caused by removal of the Centennial Site wetlands and subsequent placement of low permeability engineered fill.

## Response to Comment Grp 8-31

The commenter states that preparations for waste dumping are proposed to take place up to the boundaries for protected species, wetland, and riparian setbacks but provides no information or specifies what boundaries are referenced. The description and analysis in Chapter 4.4 of the DEIR does not indicate any location where the boundaries of proposed engineered fill piles is adjacent to the boundary of a protected area (See Figure 4.4-10 and 4.4-9 of the DEIR). DEIR Impact 4.4-3 analyzed the project's potential to impact state or federally protected waters and wetlands and determined this impact was potentially significant. Surface disturbance on the Centennial Industrial Site has the potential to impact approximately 0.033-acre of ephemeral streams. Mitigation measures 4.4-3(a-d) were identified that reduce this impact to a less than significant level. Mitigation Measure 4.4-3(b) specifically requires the applicant to prepare a watercourse/wetlands/riparian area management plan a draft of which was included as Appendix F.5. The management plan includes best management practices and erosion control to prevent discharge to Wolf Creek. In addition, the project will be required to have a constructive SWPPP that will outline similar measures to reduce erosion and sedimentation from project construction. Chapter 4.4 of the DEIR provides a through analysis of protected species and proposed mitigation to reduce impacts to protected species to a less than significant level. Mitigation Measures 4-4-1(b) has been modified in the Final EIR to require that a qualified biologist shall be onsite during all vegetation and ground disturbing activities that are within the vicinity of special-status plants.

## Response to Comment Grp 8-32

The commenter asserts that the DEIR failed to address the project's impacts to the housing market and increased homelessness, including homeless encampments in wildland areas. The commenter also states that mitigation should be provided to ensure sufficient affordable housing nearby for employees. Contrary to the commenter's assertion, the DEIR does analyze the project's impact on housing and concludes that "Nevada County has sufficient available housing stock to accommodate the entire estimated workforce for the project …." (DEIR, p. 4.9-28.) The commenter's assertion that the project could result in homelessness or encampments is speculative, as the commenter provides no evidence that the project, which would create job opportunities, could cause homelessness, or homeless encampments in wildland areas. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." As the project will not result in housing shortages, the commenter's proposed mitigation is not required.

## Response to Comment Grp 8-33

The commenter asserts that drawdown of groundwater within the underground mine may increase the potential for settlement or collapse of shallow workings. NV5 (Appendix H.6) found that the potential for geotechnical hazards associated with dewatering of the known near surface workings is low. No financial assurance mechanism is proposed, nor is required based on the low potential for any impact associated with the near surface workings. The DEIR analyzed the potential for collapse of the near surface workings in Impact 4.6-3 and concluded that the impact would be less than significant after incorporation of Mitigation Measure 4.6-3(c), which requires closure of

certain near surface mine features. The DEIR's conclusions were peer reviewed by the County's independent expert, who concurred with the conclusions. Mitigation Measure 4.6-3(c) provides clear and enforceable performance standards for closure of the near surface workings, but CEQA does not require engineering level details. (Dry Creek Citizens Coalition v. County of Tulare (1999) 70 Cal.App.4th 20, 26.) Please also see Master Response 29 - Near Surface Workings and Subsidence, and DEIR pages 4.6-12 to 4.6-15.

## Response to Comment Grp 8-34

The commenter asserts that there is potential for sinkholes to occur where undocumented mine features exist. However, this statement relates to an existing baseline condition, not an impact of the project. Regarding the settlement previously observed 100 feet south of the mapped location of the Idaho Pump Shaft, NV5 (Appendix H.5) states "Further investigation and physical closure are recommended. Rise and the property owner have entered into a cooperation agreement to allow Rise to assist the property owner to close this feature before or at the commencement of dewatering."

## Response to Comment Grp 8-35

The commenter asserts that the DEIR does not clarify liability if an unknown near surface mine working collapses as a result of dewatering. As discussed on page 4.6-44 of the DEIR, potential for collapse of existing near-surface mine features as a result of the proposed project was evaluated by NV5, whose report was independently peer reviewed by ECM. Mitigation Measure 4.6-3© requires the closure of six mine features. This impact was determined to be less than significant after mitigation. Please see Response to Comment Grp 8-33 and Master Response 29 – Near Surface Workings. As there is a low probability of settlement or collapse, the commenter's concern about liability for such collapse is speculation and is not required to be analyzed in an EIR. (See CEQA Guidelines Section 15384.)

## Response to Comment Grp 8-36

Please see Master Response 9 - Historical Mine Waste at Centennial Site. Description of the waste rock and mine tailings, including the related analytical data, are presented in Chapter 4.8 of the DEIR and the analysis of air quality and health risk assessment is provided in Chapter 4.3 of the DEIR. Geochemical testwork of mine materials is presented in section 4.4 of Appendix K.2.

## Response to Comment Grp 8-37

The commenter states that probability of mine collapse hazards have not been property addressed, because NV5 states that collapse of deep mine features is not likely to be expressed at the ground surface, but does not provide an exact percentage of occurrence. As stated on page 2 of Appendix H.6, near-surface mine features are generally more susceptible to subsidence and collapse than are deeper mine workings. NV5 (Appendix H.6) used professional judgment and experience to arrive at the conclusions presented in the document. Ultimately, the DEIR concluded that risk of collapse for deep mine workings is less than significant after mitigation. The County's independent expert peer reviewed the analysis and concurred with the conclusions.
Please see Master Response 29 – Near Surface Workings.

## Response to Comment Grp 8-38

Please see Master Response 29 – Near Surface Workings, and Response to Comment Grp 7-96 regarding seismic activity concerns.

## Response to Comment Grp 8-39
Please see the response to the referenced Faulting Hazard comment: Response to Comment Grp 7-96.

## Response to Comment Grp 8-40
Please see the response to the referenced CSP2 comment: Response to Comment Grp 7-182.

## Response to Comment Grp 8-41
Please see the response to the referenced CSP2 comment: Response to Comment Grp 7-187.

## Response to Comment Grp 8-42
Please see Master Response 27 – Greenhouse Gas Thresholds.

## Response to Comment 8-43
Please see response to referenced Baseline Comment. Response to Comment Grp 21-122.

## Response to Comment Grp 8-44
As stated on page 4.3-89 of the DEIR, The Energy Action Plan (EAP) is not a Qualified GHG Emissions Reduction Plan under CEQA pursuant to the requirements outlined in the CEQA Guidelines, Section 15183.5(D); therefore, no CEQA document can tier from the County EAP. Nevertheless, the compliance of the project with EAP strategies has been analyzed and found to be consistent with the EAP. Please see Master Response 25 - Nevada County Energy Action Plan.

Please also see Master Response 27 – Greenhouse Gas Thresholds.

## Response to Comment Grp 8-45
The commenter suggests that GHGs associated with the manufacture of cement should have been included in the DEIR. This comment pertains to a “lifecycle” analysis, which is not required under CEQA. Please see Master Response 26 – Life Cycle GHG emissions.

## Response to Comment Grp 8-46
The commenter suggests that GHGs associated with the refining of gold concentrates should have been included in the DEIR. This comment pertains to a “lifecycle” analysis, which is not required under CEQA. Please see Master Response 26 – Life Cycle GHG emissions.

## Response to Comment Grp 8-47
As discussed on page 4.7-26 of the DEIR: A permanent underground explosive storage facility will require the completion of the Service Shaft, to provide two modes of exit from the mine, in accordance with 29 CFR 1926.904(d). Therefore, until the Service Shaft construction is completed, deliveries would be made to the Brunswick Shaft and would be limited to the quantity of explosives needed for less than one week’s use during construction. Explosives would be immediately transported underground once delivered to the site. Temporary auxiliary facilities used to store explosives near underground workplaces will be in compliance with 30 CFR 57.6161 and will be wooden box type containers equipped with covers or doors, or facilities constructed or mined-out, to provide equivalent impact resistance and confinement. The commenter does not identify any impacts not disclosed by the DEIR.

## Response to Comment Grp 8-48

Please see Master Response 5 – Evacuation Zones.

## Response to Comment Grp 8-49

The commenter asserts that the DEIR does not explain the transportation and storage of the various types of detonators and that the various detonators are not listed in the hazardous materials inventory statement form submitted to the County. Section 4.7-1 of the DEIR discusses detonators and detonating cord and the transport and storage of these explosive types in relation to Hazard Class and Compatibility Group. A hazardous materials business plan is required by Mitigation Measure 4.7-1(d), which will require submittal of a hazardous materials inventory statement listing all hazardous materials that will be stored onsite. As the project has not yet been approved and the various detonators discussed in the DEIR are not in use on the project site yet, the applicant is not yet required to submit a hazardous materials inventory statement that lists those detonators.

## Response to Comment Grp 8-50

The commenter asserts that the DEIR needs to analyze the impact of heat generated by curing of concrete used by the project. However, the commenter's assertion that use of concrete in deep underground workings would create an environmental impact due to heat is speculative. The paste backfill method has been in use for about 40 years (see page 26 of Appendix H.7). The commenter provides no evidence or authority that any environmental impact or danger to workers could result. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence." Portland cement use of 25 tons per day (5% cement content in cemented paste fill) is assumed for the project as disclosed on page 295 of Appendix E.1.

No "heat management mitigations" are required or proposed for the placement of cemented paste backfill, as there is no evidence that any evidence could result. As stated on page 4 of the Itasca Deskstop Study of Cemented Past Backfill, the final formulation of the CPB, including the precise binder amount, binder source, and water content, will ultimately be defined based on rheology and strength characterization testing. This testing program will ensure that the Idaho-Maryland Mine CPB is formulated to set properly and will have sufficient strength for the intended applications within the mine.

Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d)). This process would address "long term problems in terms of chemical stability" in relation to impacts to water quality.

The preparation of detailed "thermal impact" calculations from the curing of cement backfill is not required for the purposes of analysing environmental impacts in the DEIR. Any requirements to protect workers from excessive heat would be in accordance with Mine Safety and Health (MSHA) regulations.

## Response to Comment Grp 8-51

The commenter asserts that impacts to sealed mine shafts due to dewatering were not properly addressed in the DEIR. However, near surface mine features and potential settlement/collapse due to dewatering are evaluated by NV5 in Appendix H.6 of the DEIR. Please see Response to Comment Grp 8-33.

As shown in Table 3-4 of Appendix K.2, the upper workings (Surface to 580 Level) have an estimated volume of water of 17,878,000 gallons. The water level in the New Brunswick shaft is approximately 257 feet below the top of the collar. The total water drop to 580 level is therefore approximately 323 feet. At the proposed pumping rate of 2,500 gpm, and conservatively assuming no groundwater inflow into the mine, the water in the mine would drop at approximately 2.7 feet per hour.

The water surface elevation in the mine features is expected to drop at a rate of approximately 2.7 feet per hour. This rate of drop is not expected to result in significant forces related to temporary air pressure fluctuation or increased seismicity, as further described by NV5 in Appendix P to the Final EIR.

## Response to Comment Grp 8-52

The commenter asks whether the East Eureka Shaft and East Eureka Drain will be closed prior to dewatering of the mine, and also asks if construction will be conducted underwater and/or below the top of Wolf Creek's bank. As required by Mitigation Measure 4.6-3(c) the near surface mine features, except for the South Idaho Shaft, will be closed prior to initial mine dewatering.

As stated in the mitigation measure, the closure design shall include drainage piping for those near surface features that currently discharge groundwater. This reference is to the East Eureka Shaft which currently drains water from the currently flooded Idaho-Maryland Mine. Work will not be conducted underwater or within Wolf Creek. The shaft is under the Navo & Sons building and located approximately 50 feet from Wolf Creek. The building foundation is approximately 5 feet higher than Wolf Creek. Please see the NV5 Memo, provided as Appendix P to the Final EIR.

## Response to Comment Grp 8-53

Please see Response to Comment Grp 8-52 and Response to Comment Grp 8-33.

## Response to Comment Grp 8-54

As stated in Mitigation Measure 4.6-3(c), the closure design shall include drainage piping for those near surface features that currently discharge groundwater. No concrete would be poured into water, so no interaction with drain water will occur. Please see Response to Comment Grp 8-52.

## Response to Comment Grp 8-55

As required by Mitigation Measure 4.6-3(c), the near surface mine features, except for the South Idaho Shaft, will be closed prior to initial mine dewatering. Please see Response to Comment Grp 8-33.

## Response to Comment Grp 8-56

No work within a watercourse is proposed for closure of the near surface features.

## Response to Comment Grp 8-57

The commenter asserts that water quality impacts related to cement paste backfill is not discussed in the DEIR; however, the commenter's statement is incorrect. The DEIR, at pages 4.8-46 through 4.8-49, discusses the use of CPB for backfill, describing the findings of applicant-submitted studies, third-party studies, and the peer review conducted by the County's EIR consultant team. As noted in the DEIR, "Use of CPB for the project is an environmentally favorable method for tailings disposal because it can significantly reduce any potential release of metals from the tailings and would minimize the area of surface disturbance needed for tailings disposal." (at page 4.8-47, 3rd paragraph). The DEIR also analyzes the potential for hexavalent chromium to be released from the CPB (at page 4.8-47, 4th paragraph). The DEIR concludes that, the use of CPB, along with other water management and treatment methods, and adherence to permit requirements, would avoid significant impacts to water quality. However, the DEIR considers the impacts to be significant prior to mitigation, and includes as mitigation the necessary regulatory requirements that would ensure that the project remains in compliance with water quality standards. These requirements are identified in Mitigation Measure 4.8-1(d), which are consistent with the requirements outlined in the comment letter from the Central Valley Regional Water Quality Control Board, dated April 4, 2022 (see Agency Letter 5). Mitigation Measure 4.8-1(d) requires testing of cement paste backfill for water quality impacts, and submittal of a report of waste discharge to the CVRWQCB at least 6 months prior to use of CPB, and issuance of waste discharge requirements prior to use.

The DEIR has already concluded that the use of CPB could result in a potentially significant impact related to water quality and has provided appropriate mitigation measures, consistent with the requirements of the Central Valley Regional Water Quality Control Board. Given that the DEIR already concludes that the impact could be potentially significant, and provides mitigation with regulatory oversight to ensure adherence to water quality standards, further analysis of the use of CPB is not warranted.

## Response to Comment Grp 8-58

The commenter states that the DEIR's assessments of the current mine water chemistry are inadequate. Once mine dewatering commences the flow of water through the mine workings would be altered from its current condition with water pumped up the New Brunswick shaft rather than the current mine drains. Accordingly, the commenter's suggestion that water from the mine drains be used to represent the likely water quality during dewatering would not accurately represent the water quality when the flow is altered. The DEIR's analysis including the scope of water sampling and conclusions regarding water quality were prepared by water quality experts and then reviewed by the County's independent water quality experts, who concurred with the conclusions.

The proposed water treatment plant is designed to remove iron and manganese and arsenic if it were present. Please see Master Response 5 - Discharge to South Fork Wolf Creek. As shown in Table 3.6 of Appendix K.2, zinc in the mine drains ranged from <50 to 94 ug/L and aluminum ranged from <50 to 290 µg/L. Zinc and aluminum from the drains are already less than the low threat discharge permit limits shown in Table 4-10.

The DEIR has already concluded that the project may have a potentially significant impact on water quality and has identified Mitigation Measure 4.8-1(a) to address this potential impact. This mitigation measure requires the applicant to submit a Notice of Intent (NOI) to the Central Valley Regional Water Quality Control Board (RWQCB) and the Notice of Applicability (NOA) shall be

received before initial mine dewatering can begin. The NOI shall include evaluation of potential constituents of concern and demonstrate that the water treatment plant (WTP) design shall successfully treat mine water to meet the water quality standards and treatment goals.

## Response to Comment Grp 8-59

The commenter asks how the water quality is impacted by existing timbers, whether treated wood products were used in historic mine works, and how water quality has been affected by infrastructure, equipment and spills of chemicals in the existing underground works. The items listed in bullets are related to existing conditions in the underground mine workings and, therefore, are part of the environmental baseline. The water samples collected from the New Brunswick shaft, and from Wolf Creek in 2018 were analyzed for a range of total petroleum hydrocarbons (TPH), semi-volatile organic compounds (SVOCs), volatile organic compounds (VOCs), polychlorinated biphenyls (PCBs), and mercury (See Table 3.6 of Appendix K.2). These analyses include the range of industrial chemicals described in the comment, and many others. Other than the occurrence of cis-1,2-dichloroethylene related to documented releases from the former Sierra Pacific Industries operations, there were no detections of any other organic chemicals or mercury. If future mining activity disturbs areas where some unknown residual chemicals currently reside, the monitoring required under the Central Valley Regional Water Quality Control Board WDR permits would detect any exceedances of water quality standards and the treatment systems would need to be modified accordingly to maintain compliance with discharge requirements (see Mitigation Measure 4.8-1(a)). Moreover, dewatering of the mine will allow removal of any equipment that was previously left in the underground mine, which could cause water quality impacts.

## Response to Comment Grp 8-60

The items listed in bullets are related to existing conditions in the underground mine workings. No oil products or mercury has been detected by sampling of mine water present in the underground workings. Please see Response to Comment Grp 8-59. CEQA does not require that an EIR analyze speculative impacts. As stated in CEQA Guidelines Section 15384, "[a]rgument, speculation, unsubstantiated opinion or narrative, evidence which is clearly erroneous or inaccurate, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment does not constitute substantial evidence."

## Response to Comment Grp 8-61

The commenter asserts that the mine water should be tested regularly as dewatering proceeds because of the possibility of contamination caused by oxidation of the underground rock or other contaminants such as mercury. The DEIR has already concluded that the project may have a potentially significant impact on water quality in connection with dewatering and has identified mitigation measures to address these potential impacts. As set forth in Mitigation Measure 4.8-1(a), the applicant is required to construct a water treatment plant to treat mine water to comply with applicable water quality standards prior to discharge into South Fork Wolf Creek. Moreover, the applicant is required to obtain coverage from the RWQCB for such discharge which will require testing and ongoing monitoring. Please see Master Response 5 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 8-62

Please see responses to the referenced "Sample QC Review". Responses to Comments Grp 8-134 through Grp 8-137.

## Response to Comment Grp 8-63

Please see responses to the referenced "Sample QC Review". Responses to Comments Grp 8-134 through Grp 8-137.

## Response to Comment Grp 8-64

Please see Response to Comment Grp 7-9, and Response to Comment Grp 7-164. Section 4.4 of Appendix K.2 of the DEIR provides geochemical testwork conducted on tailings and barren rock samples from the project. Testwork included Acid Based Accounting (ABA), Total Metals, and California Waste Extraction Testing (WET). The Waste Extraction Test (WET) should be used to determine the amount of extractable substance in waste rock (CCR Title 22 Division 4.5, Chapter 11, Article 5, Appendix II). The overall purpose of the barren rock and tailings sampling and laboratory analysis was to identify the general characteristics of that specific material type. Since the objective was to understand the general character, the number of samples or the length of the samples compared to the total linear feet of core drilled for mineral exploration has no relevance. As such, the results of the barren rock testing provide reliable and representative results for consideration in the DEIR and for assessment of the potential effects of the use of that material for engineered fill and cemented paste backfill.

The DEIR has already concluded that the project may have a potentially significant impact on water quality and has identified mitigation measures to address these potential impacts. Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). Please see Master Response 8 – Mine Waste Characterization.

## Response to Comment Grp 8-65

The assumed crystalline silica content and modelling of respirable silica is conservative and overestimates the relevant exposure in any situation. Therefore, sampling of materials for crystalline silica content is not required. Please see Master Response 21 – Conservatism of Silica Assumptions.

Please see responses to the referenced "Sampling Procedures". Responses to Comments Grp 7-155 through Grp 7-173.

## Response to Comment Grp 8-66

The commenter asserts that the DEIR incorrectly assesses potential for acid rock drainage, and cites to the arsenic, iron and manganese present in water discharged from the Empire Mine. However, metal content in water from mine drains is a different issue than effluent from mine wastes, and the Empire Mine has different geology than the Idaho-Maryland Mine.

Section 4.4 of Appendix K.2 of the DEIR provides geochemical testwork conducted on tailings and barren rock samples from the project. Testwork included Acid Based Accounting (ABA), Total Metals, and California Waste Extraction Testing (WET). The overall purpose of the barren rock and tailings sampling and laboratory analysis was to identify the general characteristics of that specific material type. Kinetic testing (eg ATSM D 5744) was not conducted but may be done during the RoWD/WDR process. Please see Master Response 8 – Mine Waste Characterisation. However, given the high neutralization potential of the mine materials (see table 4-8 of Appendix

K.2), it is unlikely that kinetic testing would result in the generation of acid resulting in metal leaching.

The DEIR has already concluded that the project may have a potentially significant impact on water quality and has identified mitigation measures to address these potential impacts. Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRWQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d) and engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). The waste characterization and required testwork may include using kinetic testing. Monitoring requirements will be included in the approved WDR. As such, the further testing that commenter requests will be completed as part of the RoWD process. Please see Master Response 8 – Mine Waste Characterization and Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 8-67

Please see response to referenced Baseline comment. Response to Comment Grp 21-109. Please see Master Response 8 - Mine Waste Characterization. The testwork performed on rock samples taken from the project site, and corresponding water quality analysis, was reviewed by the County's experts, who concurred with the DEIR's analysis and conclusions. Further, mitigation measures require further testing as part of subsequent CVRWQCB permitting. As such, the analysis and conclusions in the DEIR are supported by substantial evidence.

## Response to Comment Grp 8-68

As discussed on page of Appendix K.2 of the DEIR, the restoration of the post-mining discharge through the drains would be comparable to existing conditions and, thus, not an impact under CEQA. However, once the mine discharge from the drains resumed, additional compliance measures may be required by RWQCB to address Basin Plan, antidegradation, and other water quality standards. These measures might include sealing off areas of the underground workings that are the primary source of arsenic in the existing drain water, sealing the underground workings sufficiently to prevent seepage of water from the connected mine workings, obtaining an Individual NPDES permit upon closure, or treating of the mine water seeps after closure.

## Response to Comment Grp 8-69

Please see response to the referenced Baseline comment: Response to Comment Grp 21-112.

## Response to Comment Grp 8-70

Please see responses to the referenced Model Review comments: Responses to Comments Grp 7-64 through Grp 7-94.

## Response to Comment Grp 8-71

Please see responses to the referenced Model Review comments: Responses to Comments Grp 7-64 through Grp 7-94. In addition, please see Master Response 14 - Adequacy of Groundwater Model.

## Response to Comment Grp 8-72

The groundwater model used for the DEIR is appropriate for the fractured rock system at the project site. Please see Master Response 14 – Adequacy of Groundwater Model. The DEIR already provides adequate information and comprehensive analysis to determine the extent and severity of impacts to groundwater resources and wells.

## Response to Comment Grp 8-73

Please see response to referenced Baseline comment. Response to Comment Grp 21-110. The commenter mischaracterizes the DEIR's groundwater mitigation to imply that no data is collected or monitoring of groundwater is required until after dewatering commences; however, as required under Mitigation Measure 4.8-2(a) "Implementation of the GMP [groundwater monitoring plan] shall be initiated prior to the dewatering of the mine and on an ongoing basis." As such, the commenter is incorrect that groundwater monitoring and baseline data collection is deferred until after dewatering.

## Response to Comment Grp 8-74

Please see responses to the referenced Oberdorfer comments: Responses to Comments Grp 8-127 through Grp 8-133. In addition, please refer to Master Response 14 - Adequacy of Groundwater Model.

## Response to Comment Grp 8-75

The commenter states that the DEIR incorrectly assesses the transmissivity of the rock due to failure to consider the upper limit of the water level in the New Brunswick shaft. However, the observations presented in Section 3.3.3.3 of Appendix K.2 of the DEIR are not used as the basis for estimating transmissivity values used in the Groundwater Model. This section discusses the water level in the mine which remains relatively consistent with the elevations of the mine drains and is not correlated with rainfall. As the commenter mentions, and is discussed in Section 3.5.2 of the report, the water level in the mine is controlled by the elevation of the mine drains. Domestic wells, discussed in Section 3.3.2.2, show a seasonal fluctuation between wet and dry parts of the year that remained constant over many years. If a domestic well, where ground water levels are higher than the level of water in the mine, were directly connected to the mine workings, the groundwater level in the wells would be controlled by the water level in the mine. As described on page 81 of Appendix K2, the lack of a seasonal pattern in the mine water levels indicates that the mine workings are not directly connected to the wells by through-going fractures but are instead interconnected by a complex pattern of many fractures present throughout the bedrock.

Consumptive water uses from individual wells are not considered because of the lack of consumptive-use data and the fact that consumptive use is small relative to regional groundwater flow. In addition, much of the water pumped for domestic use would be recharged to groundwater by septic tanks/leach fields and landscape irrigation. Please see Itasca clarification memo attached to the Final EIR as Appendix O. In addition, please see Master Response 14 - Adequacy of Groundwater Model.

## Response to Comment Grp 8-76

The commenter states that additional data must be collected before the County can accurately model the project's groundwater impacts. Please see Response to Comment Grp 7-23. In addition, please see Master Response 14 - Adequacy of Groundwater Model. The data used for the groundwater model and the conclusions of the groundwater model, as reflected in the DEIR, were peer-reviewed by the County's independent groundwater expert, who concurred with the conclusions of the DEIR. The water level in the mine which remains relatively constant with the elevations of the mine drains and is not correlated with rainfall. The current flow rate from the drains was not used for the preparation of the Groundwater Model and therefore additional measurements would not be relevant to the analysis.

Consumptive water uses from individual wells are not considered because of the lack of consumptive-use data and the fact that consumptive use is small relative to regional groundwater flow. In addition, much of the water pumped for domestic use would be recharged to groundwater by septic tanks/leach fields and landscape irrigation. Please see Itasca clarification memo attached to the Final EIR as Appendix O.

## Response to Comment Grp 8-77

The commenter asserts that groundwater monitoring should continue for at least 5 years after the mine is closed and reflooded. However, the commenter does not identify any significant impacts that would be avoided by implementing the suggested mitigation. Monitoring is required on an ongoing basis as stated in Mitigation Measure 4.8-2(a). Therefore, monitoring would continue throughout operations and during mine closure and reclamation.

Once mining is completed, dewatering ceases, and the underground workings are allowed to flood with groundwater and are anticipated to refill over several years. No further impacts to water levels in domestic wells could occur during this period. As discussed on page 119 of Appendix K.2, after mining ceases, conditions would return to those that currently exist. The proposed new! mining activities would all occur at depths that are comparable to or much deeper than the historic! mine workings. Due to the substantial reduction in hydraulic conductivity at those depths,! compared to the depths of the domestic supply wells, it is highly unlikely that the proposed project! would affect water quality in the nearby much shallower groundwater wells. The arbitrary selection! of 5 years of monitoring after mine closure and reflooding is not supported by the analysis.! However, there will be water quality specific financial assurances for closure and post-closure! maintenance of mining units as required by Title 27 section 22510. This may include the need for! post closure water monitoring. This issue will be addressed in the approval of the WDR required! by Mitigation Measure 4.8-1(d) and 4.8-1(e).

## Response to Comment Grp 8-78

Please see Response to Comment in Group Letter 7, Response to Comment Grp 7-80.

## Response to Comment Grp 8-79

Please see Response to Comment in Group Letter 7, Response to Comment Grp 7-82.

## Response to Comment Grp 8-80

Please see Response to Comment in Group Letter 7, Response to Comment Grp 7-83.

## Response to Comment 8-81

Please see response to the referenced Baseline comment: Response to Comment Grp 21-119. In addition, please see Master Response 15 - Adequacy of Groundwater Monitoring Wells.

## Response to Comment Grp 8-82

The commenter, in part, quotes a comment from Baseline Engineering in Group Letter 21, stating that the project's potential impacts to groundwater wells are underestimated and that the proposed mitigation is inadequate. Please see response to the referenced Baseline comment: Response to Comment Grp 21-118.

The DEIR already provides adequate information and comprehensive analysis to determine the extent and severity of impacts to groundwater resources and wells. An appropriate groundwater model was used to predict impacts to domestic water wells (See Master Response 14 – Adequacy

of Groundwater Model). However, the DEIR acknowledges that without the implementation of a groundwater monitoring program and well mitigation plan, the project could result in a significant impact to groundwater supplies. A Groundwater Monitoring Plan (GMP) is required for the project under Mitigation Measure 4.8-2(a). Ongoing groundwater monitoring would be required, and groundwater-level information shall be obtained from the project groundwater monitoring wells and collected on a quarterly basis and submitted in report form to Nevada County.

The commenter references County General Plan Policy 17.12, which requires a mine operator to guarantee a supply of replacement water when "according to expert opinion" the operation may threaten quality or quantity of water. Consistent with this General Plan Policy, Mitigation Measure 4.8-2(b) requires, if based on the GMP, it is determined that mining operations are resulting in a significant impact to any well(s) (i.e., a 10 percent or greater reduction of the water column of any well), pursuant to Nevada County General Plan Policy 17.12, the Project Applicant shall be responsible for providing a comparable supply of water to such homes or businesses whose wells are significantly impacted, and if necessary, providing an immediate water supply until the source of the problem is determined and rectified. The Well Monitoring Plan is designed to predict impacts to domestic water wells before they occur. Please see Master Response 15 – Adequacy of Groundwater Monitoring.

The commenter asserts that because "expert opinion" provided in comments on the DEIR disagree with the DEIR's conclusions and the conclusions of the County's independent water supply experts, that under the General Plan policy, the County must agree with the commenters and determine that the DEIR's groundwater model is flawed. However, where there is a disagreement among experts, the County has discretion to determine which expert opinion is most reliable in the context of an EIR. CEQA case law has been clear for decades that a disagreement among experts does not make an EIR inadequate. (See, e.g., *Association of Irritated Residents v. County of Madera* (2003) 107 Cal.App.4th 1383, 1396; CEQA Guidelines § 15151.) As the California Supreme Court has explained, a reviewing court's task is not to weigh conflicting evidence and determine who has the better argument. (*Ebbetts Pass Forest Watch v. California Dept. of Forestry & Fire Prot'n.* (2008) 43 Cal.4th 936, 944.) Rather, a court "must resolve reasonable doubts in favor of the administrative finding and decision," even though other conclusions might be reached from the same body of evidence. (*Laurel Heights Improvement Assn., supra,* 47 Cal.3d at p. 422; see also *Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553, 564 [a court "may not set aside an agency's approval of an EIR on the ground that an opposite conclusion would have been equally or more reasonable"].)

As such, the County has determined that the groundwater supply analysis provided in the DEIR, and as peer-reviewed by its own independent experts is accurate, despite disagreement by commenters.

## Response to Comment Grp 8-83

The commenter alleges that the project's discharge of water into South Fork Wolf Creek will overheat the creek. Please see Master Response 32 – Temperature of Mine Water Discharge.

## Response to Comment Grp 8-84

Please see Master Response 32– Temperature of Mine Water Discharge.

## Response to Comment Grp 8-85

Please see Master Response 32– Temperature of Mine Water Discharge.

## Response to Comment Grp 8-86

Please see Master Response 32– Temperature of Mine Water Discharge.

## Response to Comment Grp 8-87

The commenter asks what the impact of using the existing clay-lined pond for pumping of mine water will be on waterfowl, riparian habitat and whether mitigation will be provided. The commenter also states that there is currently outflow from the pond into South Fork Wolf Creek; however, there is no outflow from the clay lined pond at the Brunswick site to South Fork Wolf Creek. The referenced pond is not a natural water feature, but instead is an artificial pond constructed for previous sawmill operations at the site. As discussed in Section 5.4 of Appendix K.4, the quantity of Fe, and to a much lesser extent Mn, removed from the mine waters by aeration treatment and stored in (settled to the bottom of) the pond is relatively small. Periodic backwashes of the media vessels will release filtered and adsorbed solids. The backwashes will be directed to a mechanical solids removal system and stored in containers rather then directed back into the pond. The mass of solids removed during backwashing is small, estimated at 3 kg to 10 kg per day (page 44 of Appendix K.4). The purpose of the water treatment system is to improve the quality of mine water. Aeration in the pond will cause most iron to precipitate from its dissolved state in the water and settle towards the bottom of the pond. If arsenic is present it would precipitate with the iron. Manganese would primarily be removed in the water treatment plant and would not be backwashed into the pond. Therefore, water in the pond will have less iron, arsenic, and manganese than water from the mine.

As stated on page 4.4-15 of the DEIR: "*A man-made clay lined pond (PD-1) associated with previous saw milling operations does not have a direct outlet or connection to the South Fork Wolf Creek. PD-1 receives its water mainly from surface runoff and precipitation. PD-1 was used previously as a recycling pond for site runoff containment and log watering during mill operations. PD-1 is non-jurisdictional pursuant to federal Clean Water Act (CWA) regulations given it receives water from sheet flow within the Brunswick Industrial Site and does not connect directly or indirectly with South Fork Wolf Creek or any other 'waters of the U.S.'.*" As stated above, the water treatment pond is an artificial pond constructed for industrial uses. As such, the pond berms are not riparian areas and vegetation on the structure will be removed. Untreated water in the pond would not be released to the environment. No mitigation to replace habitat in the pond is proposed nor required. As discussed in Section 3.4.1.1 of Appendix K.2, the water in the mine contains only Iron and Manganese above water quality guidelines. In the case of Iron and Manganese, water quality guidelines are based on the secondary drinking water standards (taste and odor) and neither has maximum contaminant level (MCL) for aquatic life. Furthermore, acute toxicity test conducted on water from the New Brunswick shaft had a 100 percent survival rate for rainbow trout (see page 41 of Appendix K.2). Ammonia, from explosives use, could be present in mine water during operations but would be removed during water treatment by aeration in the water treatment pond (see page 4-5 of Appendix K.4).

## Response to Comment Grp 8-88

Service water for the mine would be from the water treatment plant, and will therefore be treated water. The requirements for treatment of contaminants under the limited threat permit are equal to or better than drinking water standards. Regarding discharge of contaminants into the environment from the pond, see Master Response 35 - Discharge to South Fork Wolf Creek.

## Response to Comment Grp 8-89

The commenter asks whether water will be tested before use in cemented paste backfill. Cemented paste backfill is non-draining and uses some water for cement hydration and retains the remaining water within its matrix (see page 2 of the Cemented Paste Backfill Study). Given that no water would drain from the cemented paste backfill, the water used in cemented paste backfill could not cause future groundwater contamination, and testing of process water is not required. Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Control Board (CVRQCB) prior to the placement of cemented paste backfill (Mitigation Measure 4.8-1(d). This process would require that effluent from backfill meets water quality goals.

## Response to Comment Grp 8-90

As discussed in the DEIR (page 4.11-36), water used for dust suppression would be treated water from the water treatment plant or water purchased from the Nevada Irrigation District. Untreated mine water would not be used for this purpose.

## Response to Comment Grp 8-91

Odor from the water treatment pond has been analyzed and found to be less than significant (see page 56 of DEIR Appendix E.1). No air quality impacts are expected from the aeration process, and no evidence has been provided that any potential for impacts exist.

## Response to Comment Grp 8-92

Mitigation measures require the applicant to submit a Report of Waste Discharge (RoWD) and receive an approved Waste Discharge Requirement (WDR) from the Central Valley Regional Water Quality Control Board (CVRQCB) prior to the placement of engineered fill (barren rock and sand tailings) (Mitigation Measure 4.8-1(e)). The requirements for testing and materials management, to ensure water quality goals are achieved, will be specified in the approved WDR.

Water used for dust suppression would be treated water from the water treatment plant or water purchased from the Nevada Irrigation District. Untreated mine water would not be used for this purpose. Please see Master Response 1 - Engineered Fill Utilized in Local and Regional Construction Markets; and Master Response 8 - Mine Waste Characterization.

## Response to Comment Grp 8-93

The commenter asserts that the water treatment pond will need to be drained and cleaned periodically to remove sediment; however, this is not correct. As discussed in Section 5.4 of Appendix K.4 to the DEIR, the removal of sludge from the water treatment pond can be achieved with slurry pumps. Therefore, the periodic removal of settled solids would not require the curtailment of mine dewatering or the draining of the water treatment pond.

As stated on page 5-3 of Appendix K.4 to the DEIR, the solids removed from the water treatment pond will be dewatered and hauled to an appropriate and approved off-site landfill. Testing will be conducted in accordance with the sampling requirements and acceptance criteria of the landfill.

## Response to Comment Grp 8-94

The commenter asserts that the use of the New Brunswick Shaft is not proper because of the proximity to a known fault, and that the main processing and access facilities should instead be placed on the Centennial Site. As discussed in Section 4.5-1 of the DEIR, based upon substantial

evidence in the record, the project includes a request to amend the Final Map for Bet Acres recorded in February 1987 in Book 7 of Subdivision Maps at Page 75 to remove the "200' Building Setback From Fault", as shown on Sheet 4 of Final Map #85. The County's independent geotechnical consultant agreed that the removal of this setback is proper, given the lack of evidence to indicate an active fault at this location (see pages 4.6-3 to -5 of the DEIR).

In addition, a management plan was prepared pursuant to Nevada County LUDC Section L-II 4.3.8 to address potential seismic hazards associated with the previously-identified inferred fault alignment. It is NV5's professional opinion that the subject fault, identified on the property in Map 85-7, does not qualify as a seismically active area as defined by Nevada County LUDC Section L-II 4.3.8.B, and the proposed project development within the designated building setback fault zone is generally feasible from a geotechnical engineering standpoint.

While the analysis shows that an active fault likely does not exist, out of an abundance of caution, the County has concluded that a significant impact could occur without mitigation. Mitigation Measure 4.6-1 requires that prior to approval of Improvement Plans, the design recommendations from the Brunswick Industrial Site Geotechnical Report (November 18, 2019) shall be incorporated into the Plans to the satisfaction of the Nevada County Building Department.

The commenter also suggests that the County should consider placing the access shafts and processing facilities on the Centennial Site rather than the Brunswick Site because Emgold previously planned to do so and that multiple access points from different parts of the mine provides better emergency access and ventilation. A vertical shaft at the Centennial site is not a practical solution as it is far west of the area of mineralization at depth (See sheet 15 of Appendix K.2) and would intersect the serpentinite rock unit (see Sheets 5-7 of Appendix K.2), causing potential geotechnical issues. The 2008 Emgold DEIR[3] proposed to construct a decline tunnel from the Centennial site to access the underground mine and haul rock from underground to surface using trucks (See page 2-23 of ESA 2008). A decline tunnel must be at a gradient allowing wheeled trucks to haul materials to surface, typically 10% to 15% grade, and therefore is much longer than a vertical shaft which greatly increases the energy required to move materials to surface versus a shaft. Significantly more rock excavation volume would also be required for a decline tunnel versus a shaft. If the process plant were located at the Centennial site very little or no engineered fill could be placed at the Centennial site and all fill would be hauled and placed on the Brunswick site. The process plant would be further from residential properties. However, the DEIR has analyzed noise, air emissions, odor and other impacts associated with the currently proposed location of the process plant which are already less than significant after mitigation. Moreover, The commenter does not identify any significant impacts that would be avoided by adopting the suggested alternative and the proposed alternative would likely increase impacts; therefore, this proposed alternative is dismissed from further consideration.

## Response to Comment Grp 8-95

Please see response to referenced faulting hazard comment: Response to Comment Grp 7-96.

## Response to Comment Grp 8-96

The Commenter asserts that a variance should be denied relating to the building setback from a fault. However, the applicant is not requesting a variance from the setback requirement, but rather

[3] ESA (Environmental Science Associates). (2008). *Draft Idaho-Maryland Mine Project Environmental Impact Report* San Francisco, California.

is requesting that a note on the subdivision map referring to the setback be removed given the lack of evidence supporting the existence of an active fault at this location.

## Response to Comment Grp 8-97

The commenter asserts that alternative land uses are not adequately discussed in the DEIR, and claims that a project consistent with the existing zoning would be more appropriate for the site. As stated on 6-13 of the DEIR, numerous industrial uses are already allowed on the Brunswick Site without the need for a use permit from the County, such as Auto Dismantling Yards and Wholesaling and Distribution Facilities. The DEIR discloses that these types of uses could cause substantial noise, traffic, aesthetic and air quality impacts without the need for further CEQA review or mitigation, as discretionary permits are not required for those uses. Given that the existing zoning allows uses that could likely be more intense and impactful than the project in numerous resource areas (e.g., noise, air quality, traffic), the County dismissed this Alternative from further consideration (DEIR p. 6-13.). Please also see Response to Comment Grp 21-104.

## Response to Comment Grp 8-98

As stated on page 4.9-3 of the DEIR, "While the majority of the Sites are located in the City's sphere of influence and assigned General Plan land use designations by the City, the Sites are located within unincorporated Nevada County and are not proposed to be annexed to the City of Grass Valley." The County evaluated potential land use conflicts in Chapter 4.9 of the DEIR and concluded that potential land use conflicts were less than significant.

## Response to Comment Grp 8-99

The commenter states that the DEIR must determine whether the dumping of mine waste is a heavy industrial activity. As stated on page 4.9-16 of the DEIR, Surface mining, including the production and disposal of mining waste, are allowed in the M1 (light industrial) district where the property is Zoned ME, subject to the approval of a Use Permit. The Brunswick site will be zoned M1-ME if the project is approved. The objective of the placement of engineered fill, over approximately 5 years, at Centennial site is to increase the usable land area at the Centennial site to allow its future use as industrial land (see page 3-12 of the DEIR) and no other activities are proposed for this site ;therefore, this is properly considered a construction activity allowed on the Centennial site. As stated in Section L-II 3.22 D.4.b of the Nevada County Land Use and Development Code, on-site excavation and on-site earthmoving activities which are an integral and necessary part of a construction project that are undertaken to prepare a site for construction of structures, landscaping, or other land improvements, including the related excavation, grading, compaction, or the creation of fills, road-cuts, and embankments are exempt from Section L-II 3.22 and the requirement for ME zoning.

## Response to Comment Grp 8-100

The culvert present at the Brunswick site is part of the existing condition and prior permitting for construction is not relevant to the analysis for the DEIR.

Recorded easements on the Brunswick site have been plotted by a Licensed Land Surveyor. No project activities are proposed in the location of the 100-foot NID spill easement.

https://www.nevadacountyca.gov/DocumentCenter/View/30408/Brunswick-Site-Easements---NCE

## Response to Comment Grp 8-101

The commenter asserts that the DEIR should analyze the "Weimar" fault and show the location of proposed structures in relation to this fault. As discussed in Section 4.5-1 of the DEIR, based upon substantial evidence in the record, the project includes a request to amend the Final Map for Bet Acres recorded in February 1987 in Book 7 of Subdivision Maps at Page 75 to remove the "200' Building Setback From Fault", as shown on Sheet 4 of Final Map #85. The County's independent geotechnical consultant agreed that the removal of this setback is proper, given the lack of evidence to indicate an active fault at this location (see page 4.6-4 of the DEIR).

In addition, a management plan was prepared pursuant to Nevada County LUDC Section L-II 4.3.8 to address potential seismic hazards associated with the previously-identified inferred fault alignment. It is NV5's professional opinion that the subject fault, identified on the property in Map 85-7, does not qualify as a seismically active area as defined by Nevada County LUDC Section L-II 4.3.8.B, and the proposed project development within the designated building setback fault zone is generally feasible from a geotechnical engineering standpoint.

While the analysis shows that an active fault likely does not exist, out of an abundance of caution, the County has concluded that a significant impact could occur without mitigation. Mitigation Measure 4.6-1 requires that prior to approval of Improvement Plans, the design recommendations from the Brunswick Industrial Site Geotechnical Report (November 18, 2019) shall be incorporated into the Plans to the satisfaction of the Nevada County Building Department.

## Response to Comment Grp 8-102

The commenter states that a map with the South Idaho Shaft shown in relative location to Pine Hill flannelbush locations must be provided to protect these plants. The South Idaho Shaft is inside the area of proposed placement of engineered fill at the Centennial site, and a total of 18 plants will be transplanted under Mitigation Measure 4.4-1(a). Impacts to flannelbush plants have therefore already been analyzed in the DEIR, mitigation has been provided, and the DEIR concluded that impacts would be less than significant after mitigation (See DEIR, Impact 4.4-1). In addition, please see Response to Comment Grp 8-24.

## Response to Comment Grp 8-103

A map showing the mineral rights area is included as Figure 3-2 to the DEIR. There is no requirement that a map identifying each parcel within that area be provided.

## Response to Comment Grp 8-104

Please see response to referenced Salter comment. Response to Comment Grp 21-130.

## Response to Comment Grp 8-106

Please see response to referenced Salter comments. Responses to Comments Grp 21-142 through Grp 21-144.

## Response to Comment Grp 8-107

The comment expresses concern with blasting vibrations and long-hole stope blasting, which was studied extensively in the DEIR. Note that the commentor incorrectly refers to stope blasting as "slope" blasting. Vibrations from long hole blasting are discussed extensively in Section 4.10-4 of

the DEIR and Appendix M of the DEIR and are determined to be less than significant. (DEIR pp. 4.10-26, 4.10-52, and Table 4.10-23.) As shown in Table 4.10-22 and Table 4.10-23, all groundborne vibrations calculated for blasting of both drift round and long-hole stopes, respectively, fall below the USBM recommendations and the levels at which structural damage to buildings is possible (see Table 4.10-9). Drift development blasts at the shallowest depth considered of 500 feet would be barely perceivable to the general population and undetectable by instrumentation below 900 feet in depth. Larger longhole stoping blasts at the shallowest depth considered of 500 feet would be 0.23 in/s, which is also well below the threshold level of vibration (0.4 in/s). (DEIR p. 4.10-54.)

The maximum potential noise and vibration caused by falling rock is trivial in comparison to what has already been analyzed in the EIR. Please see Response to Comment Grp 8-108.

## Response to Comment Grp 8-108

This comment alleges that ground vibrations from falling rock in the new access shaft should be considered. As discussed on page 3-22 of the DEIR, the proposed service shaft excavation in rock would be constructed from the underground mine workings upward to the surface through a process called 'raising'. The raise excavation could be completed using either mechanical raise boring or Alimak raising. Raise boring is carried out using a raise bore machine located on the surface. A drill hole is made from the surface to the underground workings. After a cutting head is attached underground to the end of the drill pipe, the raise bore machine pulls the rotating cutting head upward to create a circular excavation in a continuous process. Alimak raising is carried out using drilling and blasting. The raise is blasted from the bottom upward. Rails are attached to the wall of the raise so that an Alimak raise climber can lift the miners to the working face. An Alimak raise is advanced with each blast in segments of approximately 10 feet.

Ground vibration from construction of the service shaft is analyzed in section 5.0 of DEIR Appendix M. The highest levels of ground vibration will be that produced from the breakthrough round, as this has the least amount of vertical distance between the blast and the surface. While this round will be 50 ft below surface it will be blasted to the surface. This is an extremely conservative estimate both in the magnitude of estimating the ground vibration and assuming there is no vertical relief. (DEIR p. 4.10-58.)

The ground vibration from this single shot would not be expected to cause damage to industrial structures adjacent to the raise breakthrough round or residences in the area. At maximum, the ground vibration at the nearest receptor is expected to be 0.13 in/s which is well below the 0.4 in/s recommendation for human perception. (DEIR p. 4.10-58; see also DEIR Table 4.10-9.)

Air overpressure from construction of the service shaft is analyzed in the Technical Blasting Report section 5.0 of DEIR Appendix M. The single breakthrough round from the shaft may produce air overpressure of 126 dB, which is approximately 50% of the U.S. Bureau of Mines recommendations. The U.S. Bureau of Mines and the Office of Surface Mining, Reclamation, and Enforcement (OSMRE) have both developed recommendations for ground vibration levels to prevent damage to residential structures. These recommendations will be strictly followed by the project. Regarding site-specific analysis and recommendations, Dr. Konya of Precision Blasting Services recommended a threshold level of 0.4 in/s PPV for the Idaho-Maryland Mine project. (DEIR p. 4.10-21; See also DEIR Table 4.10-9.)

During the construction of the Service Shaft, assuming it is constructed by Alimak raising, rock would fall up to 1,000 feet inside the excavation after blasting. Section 7 of the Federal Transit Administration Transit Noise and Vibration Impact Assessment Manual (September, 2018) provides guidance for evaluating noise and vibration during construction activities. (DEIR p. 4.10-20.) While it does not provide reference data for evaluating vibration levels for falling rock, it does provide data for impact-type pile drivers which is analogous to vibration levels from falling rock. Table 7-4 on page 184 of the FTA publication reports a maximum vibration level of 1.5 in/sec peak particle velocity for impact-type pile driving activities at a distance of 25 feet from the location where impact would occur. This level of vibration is trivial in comparison to the level of vibration already analyzed for the concurrent detonation of explosives. Assuming a charge weight of 42.1 pounds and the formula presented on page 6 of Appendix M of the DEIR, the PPV from the blast at 25 feet can be calculated at approximately 15 in/sec. The charge weight for a longhole blast is assumed at 133 pounds and PPV at 25 feet can be calculated as above at 28 in/sec. As seen from the foregoing, the maximum potential vibration caused by falling rock is trivial in comparison to what has already been analyzed in the DEIR. Noise from falling rock at the blasting area would also be far lower than noise from the explosive's detonation and noise from blasting at sensitive receptors on surface is less than significant (see page 4.10-44 of the DEIR). Therefore, noise from falling rock would also be less than significant.

## Response to Comment Grp 8-109

The commenter asks how long the construction of the new access shaft will take, how long after initiation of site construction before the access shaft will be constructed, and how long after the initial dewatering of the mine the shaft will be constructed. The service shaft must be completed before production mining can commence in accordance with MSHA regulations. Construction of the access shaft is generally expected to take 12 months. However, the precise timing will be dependent upon the timing necessary to obtain other ancillary permits and approvals, which cannot be known precisely in advance. The exact timing of access shaft construction is not necessary for the analysis of environmental impacts in the DEIR.

## Response to Comment Grp 8-110

The recommendation cited by the commenter was incorporated into Mitigation Measure 4.10-4 of the DEIR.

## Response to Comment Grp 8-111

Please see Master Response 11 - Engineered Fill Utilized in Local and Regional Construction Markets.

## Response to Comment Grp 8-112

As described in Section 3.0 of the DEIR, after full placement of fill at the Centennial and Brunswick Industrial sites to the pad design elevations, hauling of engineered fill (barren rock and sand tailings) would shift entirely to be utilized in local and regional construction markets. Please see Master Response 11 – Engineered Fill Utilized in Local and Regional Construction Markets.

No large-scale temporary storage facilities are proposed for the project, and placement of such stockpiles would not be allowed under the project's conditional use permit. The project includes temporary storage of materials at the Brunswick Shaft, inside the process plant, and at the Brunswick and Centennial sites where material would be dropped by trucks and later graded and compacted during weekday daylight hours.

## Response to Comment Grp 8-113

Please see Group Letter 7, Response to Comment Grp 7-3, and Master Response 24 - Project Construction Schedule.

## Response to Comment Grp 8-114

The southwest portion of the water treatment pond berm would be excavated and rebuilt before dewatering commences; and the clay liner of the pond will be covered with a geomembrane liner to ensure no seepage from the pond occurs. (See page 3-17 of the DEIR). The impacts of the project construction to surface waters and wetlands have already been assessed in the DEIR and mitigation measures are required to reduce impacts to a less than significant level. (See Impact 4.4-3 of the DEIR.) The pond would be drained to allow the reconstruction of the berm and installation of the liner. If the water is discharged to South Fork Wolf Creek, it would be required to be in compliance with the approved Notice of Applicability (Please see Master Response 35 – Discharge to South Fork Wolf Creek). Alternately, the water drained from the pond may be discharged to land (and recharge into the ground) under the requirements of the Construction Stormwater Pollution Prevention Plan (C-SWPPP) required by Mitigation Measure 4.8-1(b) of the DEIR.

## Response to Comment Grp 8-115

The headframe height is required to lift the rock skips high enough to drop hoisted rock into the existing shaft silo. The process plant height is required for the tailing dewatering sections where materials use gravity flow and sufficient height is needed for the various machinery. Placement of these structures below ground is not technically feasible, as the bottom of the structures need to be accessible at surface level to allow loading of trucks. As such, the suggested mitigation is not considered further due to infeasibility.

## Response to Comment Grp 8-116

This comment summarizes the prior comments and generally asserts that the DEIR is inadequate and needs to be recirculated. The commenter's specific comments are addressed in Responses to Comments Grp 8-1 to Grp 8-117.

## Response to Comment Grp 8-127

This comment is a summary of comments Grp 8-128 to Grp 8-133. Please see Responses to Comments Grp 8-128 through Grp 8-133. The commenter asserts that the groundwater model is flawed because it does not include shallow groundwater levels in 1956 towards the end of historic mining.

The commenter is confused on several main issues.

1) The commentor believes that drawdowns are shown relative to 1956 when the mine was dewatering. This is incorrect. The drawdowns are shown relative to 2019 (or current) ground water levels. The reason for using 2019 groundwater levels is because they are the equilibrium conditions under current landscape and hydrogeologic conditions. All water supplies of domestic wells are controlled by the current water levels not the 1956 water levels.
2) The commentor is confused between the level of water in the mine and the groundwater level. The groundwater level is influenced by the level of water in the mine (creating drawdown cones) but they are not the same. In most mining operations, the water level in the mine is below the mine working in order to maintain the dry working conditions. Because the rock has low hydraulic conductivity, there will be a large difference between the groundwater levels in the rock mass and groundwater level in the mine working. The lower the permeability is, the larger the resistance from groundwater in the surrounding rocks mass to flow to the mine workings is and, consequently, the larger difference between groundwater levels in the rock mass and mining working is.
3) The commenter is using a different definition of “initial condition” than is used by Itasca in the Groundwater Model Report. The commenter believes that “initial condition” is the

baseline for the measurement of project impacts. This is not correct. This point is explained in Bullet Item 1.

As the commenter is mistaken about the groundwater model that was used in the DEIR, the commenter's specific critique of the model is based on a misunderstanding. The groundwater model was calibrated by experts in groundwater modelling and peer-reviewed by the County's own groundwater experts and constitutes substantial evidence of the DEIR's conclusions.

## Response to Comment Grp 8-128

The commenter states that the groundwater model is flawed because of the initial conditions assumed by the model; however, the commenter misunderstands how the groundwater model works and is therefore mistaken. As explained in Section 4.0 of Appendix K.3, the initial condition was modelled in the following general sequence:

1) Simulation of pre-historical mining conditions (before any mining had taken place). No groundwater levels are available for the model calibration of pre-historical-mining groundwater conditions. Itasca assumed that 2019 water levels outside of the Mine area are close to those of the pre-historical-mining condition after more than 60 years of recovery. This assumption is supported by the available hydrographs from domestic wells (Todd 2007), which show that groundwater levels were generally stable from 1994 to 2007 with seasonal variations. Therefore, it is reasonable to use these measured water levels for the calibration of the pre-historical groundwater levels-
2) Simulation of historical mining. Using the simulated groundwater levels of the pre-historical mining condition, Itasca calibrated the model using the known inflow rates and underground mine workings from two periods of mining. The Idaho mine in 1918 and the entire connected Idaho-Maryland-Brunswick mine in 1956. The model was also calibrated against the known level of water in the Union Hill mine in 1956. (Section 4.6 pages 21-22)
3) Recovery of groundwater level after the cessation of historical mining to present day. The drain nodes for the historical mine workings were turned off and mine voids were simulated with a zone of high K and the drains along Wolf Creek (which currently drain the mine) were added at their known elevation. (Please see Itasca Clarification Memo attached to the Final EIR as Appendix O). The simulated recovered water levels were then compared against the water levels measured in wells in the mine area from 1994 to 2007. Measured groundwater levels from the domestic wells are not available since 2007. However, it is reasonable to assume that these groundwater levels are somewhat stable with the exception of seasonal fluctuations, as no major pumping (stresses) has occurred since 2007. The model was found to be calibrated to the assumed current (2019) measured water levels. (Section 4.5 page 22).
4) The simulated 2019 (current condition) water levels are the baseline for measuring impacts from the proposed project. This baseline models the current situation of groundwater draining from the mine working into Wolf Creek and under the current hydrogeologic condition.
5) The simulated water levels after the mine is dewatered by the proposed project would be similar to the water levels in 1956 at the end of the historical mining. Therefore, it is reasonable to assume the predicted drawdown at the end of dewatering of the existing mining workings as proposed by the project will be similar to the drawdown at the end of the historical mining in 1956. Additional drawdown will occur due to the planned future mining of the project. Therefore, the simulated groundwater levels in 1956 are used as the

initial condition for predicting the effects of new mining proposed by the project. (Section 5.1 page 23)

The commenter refers to Figure 5-7, but it appears that reference is in error. Figure 5-7 of Appendix K.3 shows the change in baseflow rate in creeks over the life of the mine. Presumably the commenter is referring instead to Figure 5.4 which shows the simulated groundwater drawdown contours at the end of future mining (25 years) relative to the 2019 water level.

The commenter states "the incremental drawdown from increasing dewatering from 700 gpm to the future rate of 900 gpm is what is reflected in the map of impact." The commenter previously indicates that dewatering at a rate of 700 gpm = the water levels at the end of mining in 1956; however, the commenter is incorrect. As is explained in bullet 4 above, the baseline used is the 2019 (current condition) and not the 1956 water levels (dewatered mine). The title block of Figure 5.4. clearly states "Relative to 2019 Water Level".

Figure 5.4 is a large-scale figure but shows a small drawdown cone at the Union Hill mine. Sheet 12 of Appendix K.2 of the DEIR (which is plotted from Itasca's data) shows more definition with a 10-foot drawdown contour at the location of the Union Hill Mine shaft. This is more than the few feet stated by the commenter. The groundwater drawdown is the relative level of the groundwater and not the level of water that is in the mine shaft. The commenter is confusing the historic level of water level in the Union Hill mine shaft (20 feet) with the ground water level in the area of the shaft. Furthermore, as discussed in bullet 2 of this response, the model was specifically calibrated against the historic water level in the Union Hill Shaft.

The commenter appears to confuse directions in its comment by claiming that the New Brunswick shaft is west of the Union Hill mine. The New Brunswick shaft is east of the Union Hill mine rather than west. Additionally, the commenter confuses the water level in the shaft/mine workings with the ground water level. As previously explained, the commenter is incorrect about the baseline which was used for predictive modelling. The initial condition is not the baseline as explained in bullets 4 and 5 of this response.

As the commenter is mistaken about the groundwater model that was used in the DEIR, the commenter's specific critique of the model is based on a misunderstanding. The groundwater model was calibrated by experts in groundwater modelling and peer-reviewed by the County's own groundwater experts and constitutes substantial evidence of the DEIR's conclusions.

## Response to Comment Grp 8-129

Please see Responses to Comments Grp 8-127 through Grp 8-128. The baseline used is the 2019 (current condition) and water drawdowns shown and used to determine impacts are relative to the 2019 (current condition) and not the dewatered mine (as at 1956 and after initial dewatering by the proposal project). As the commenter's understanding of the groundwater model's assumptions are incorrect, the commenter's conclusions about the effects of dewatering are also incorrect.

## Response to Comment Grp 8-130

The commenter asks for a drawdown map and groundwater elevation contour map for the shallow aquifer based on 1956 conditions before cessation of dewatering. To provide additional clarity on the impact of the project to groundwater levels, Sheet #16 has been attached to the Final EIR which shows relative ground water levels after initial mine dewatering (before new mining

commences) which is the same as modelled groundwater levels in 1956. The information provided in Sheet 16 is consistent with the analysis in the DEIR and does not change any impact analysis.

## Response to Comment Grp 8-131

The commenter requests detailed hydrographs of simulated water levels from 1920 (When the Idaho mine was dewatered) through 2020 (current condition) and for 25 years of planned mining. The commenter requests these for the location of wells WS95, WS216, WS201, WS80, WS91, and WS85 on Figure 2-6 of Appendix K.3. The wells chosen by the commenter are the wells highlighted in the figure and spread over several miles in or near the mineral rights area for the project.

The hydrographs requested by the commenter are not necessary because the goal of the predictions is to show the location and the magnitude of the estimated drawdowns. The commenter does not explain how the hydrographs would be used or how they would alter the conclusion in the DEIR that the project could have a potentially significant impact with respect to groundwater supplies.

The goal of the predictions prepared in the groundwater model is to show the location and the magnitude of the estimated drawdowns relative to the baseline (2019 current condition) in order to determine the potential impact of the project to domestic water wells. Simulated drawdown contour maps, relative to the baseline, have been produced for all relevant periods of the project.

## Response to Comment Grp 8-132

The commenter requests a detailed model water budget (all volumetric water inputs and outputs) for the general area of the mineral rights from 1920 (When the Idaho mine was dewatered) through 2020 (current condition) and for 25 years of planned mining in one-month increments.

The goal of the requested water budget is not apparent. The commenter does not explain how monthly water budgets would be used or how they would alter the conclusion in the DEIR that the project could have a potentially significant impact with respect to groundwater supplies.

The goal of the predictions prepared in the groundwater model is to show the location and the magnitude of the estimated drawdowns relative to the baseline (2019 current condition) in order to determine the potential impact of the project to domestic water wells. As the DEIR already concluded that the impact could be significant, and estimates drawdown in the vicinity of the project site, a water budget is not necessary to complete this goal.

## Response to Comment Grp 8-133

The commenter asks that the model should be run using 2019 water levels as the initial conditions for predictive simulations. However, the model already shows impacts relative to the 2019 (current conditions). The commenter is using a different definition of “initial condition” than is used in the Itasca Groundwater Model Report (Appendix K.3). Please see Responses to Comments Grp 8-128 and Grp 8-129.

Hydrographs are not necessary for the analysis. Please see Response to Comment Grp 8-131.

Water budgets are not necessary for the analysis. Please see Response to Comment Grp 8-132.

## Response to Comment Grp 8-134

The commenter questions the validity of the DEIR's conclusions, because of the amount of time that the samples were held prior to testing. As noted in the comment, SW-846 provides guidance but is not applicable in all situations. Furthermore, as noted in the EPA Memo 7 related to SW-846 (https://www.epa.gov/sites/default/files/2015-10/documents/memo7.pdf):

> "SW-846 contains the analytical and test methods that EPA has evaluated and found to be among those acceptable for testing under subtitle C of the Resource Conservation and Recovery Act (RCRA). In most situations, SW-846 functions as a guidance document setting forth acceptable, although not required, methods to be implemented by the user, as appropriate, in responding to RCRA-related sampling and analysis requirements. The methods are intended to be used and modified, as needed, to promote unbiased, sensitive, precise, comparable, and specific analyses and test results. In addition, with the exception of method-defined parameters (e.g., Method 1311, the Toxicity Characteristic Leaching Procedure), SW-846 methods need not be applied in a prescriptive manner. "

Notably, the SW-846 guidance was specifically developed for use in evaluating the presence of human-created hazardous wastes under programs related to the Resource Conservation and Recovery Act. Its application has since expanded to include Superfund evaluations and other sites related to man-made releases of toxic substances. Due to the prevalence of these types of sites, the guidance provided by SW-846 became standard operating procedure for analytical laboratories. However, the sample holding times and preservation methods are not universally applicable under all conditions.

The baseline evaluations conducted for the Idaho-Maryland Mine were conducted on native materials (surface water, groundwater, rock) and were not part of an analysis related to RCRA or to assess the presence of existing waste materials. Thus, the guidance in SW 846 is just that, guidance, but it does not represent a strict set of procedures that must be followed for the data to be usable for the purposes of this EIR.

The analyses related to metals were conducted on native geologic material that have been present in the environment for many millions of years. The purpose of the testing was to assess the potential for actions related to the proposed project to mobilize naturally-occurring metals within the minerals in the rock. The time between collection of the rock sample and the lab analysis, and the temperature at which the rock samples were stored or transported, has no effect on the presence or mobility of the naturally occurring metals within the rock itself. This is in stark contrast to the sampling that is typically conducted under the programs, such as RCRA, for which SW 846 was developed. In those cases, the sampling and analysis is typically intended to evaluate the presence of chemicals that were added by human activity and whose presence and nature tend to be transient. As such, the hold times for the rock samples do not affect the validity of the results or the validity of the DEIR's analysis.

## Response to Comment Grp 8-135

The hold times do not apply since the analyses were being conducted on rock samples for metals that are a part of the naturally occurring minerals in the rock. Please see Response to Comment Grp 8-134.

Potential for loss of mercury under the conditions described could be of concern if the testing was being conducted on materials that may contain elemental mercury. However, the samples were all from drill core in native geologic formations that do not contain mercury mineralization and that

were not a part of any past operations at the Idaho-Maryland Mine. Thus, any mercury that could potentially be present would be trace amounts that might be part of the mineral matrix in the naturally occurring geologic formations. Extended hold times and temperatures above 6 degrees Celsius would not affect the presence of mercury in the samples since the natural rock has been present for millenia and exposed to a wide range of temperature variations over that period.

As noted in Table 4-7 of Appendix K.2 of the DEIR, boron was not detected in any of the samples analyzed, so there is no potential that boron could have leached from glass sample containers.

The notations from ACZ noted in this comment are not relevant to the samples that were actually analyzed. Testing for chloride, nitrate, nitrite, and sulfate were not conducted on the solid rock and tailings samples provided to the laboratory. Instead, the lab was requested to conduct a wet chemistry analysis on the DI-WET leachate after the leaching was completed (see Chain of Custody forms on EMKO Appendices pp 318-319). Testing for wet chemistry parameters such as the anions listed above is not possible on dry rock samples. Thus, the sample did not even exist until it was created by the lab. Holding times and sample temperature have no bearing since the sample was created and subsequently analyzed directly in the lab.

According to California State Certificate of Environmental Laboratory Accreditation Certificate No.: 2935 (https://acz.com/wp-content/uploads/2021/11/California.pdf), ACZ is certified to analyze boron, sulfate, and solids (filterable, non-filterable and settleable) in non-potable water but ran the analyses using methods for hazardous waste instead, which do not include certification for those analytes.

The analyses not offered for certification or are not covered by NELAC certification #ACZ were conducted as part of the acid-base accounting evaluation. ACZ Laboratories holds certification from the State of Nevada for acid-base accounting methods. Nevada is currently the only state agency offering this certification. https://acz.com/index.php/geochemistry/. Please see Response to Comment Grp 7-167.

## Response to Comment Grp 8-136

The holding time for coliform bacteria tests is 6 hours, which presents a challenge for typical field sampling programs where the time to collect multiple samples and then deliver the samples to the laboratory often cannot be completed within 6 hours. This occurred with the sampling at the New Brunswick shaft where obtaining a single sample sometimes required more than an hour and the work occurred overnight. The sampling conducted was to assess baseline conditions, however, and has no bearing on the finding of significant impacts from the project related to water quality. Please see Master Response 35 - Discharge to South Fork Wolf Creek.

Field measurements of pH are provided in Tables 3-5, 3-8, and 3-10 of Appendix K.2.

Comments on hold time exceedance for samples D-1 and ED-1 for BOD, MBAS, $NO_3$, and $NO_2$ are noted and acknowledged. The accuracy of these results do not have any bearing on the finding of significant impacts from the project related to water quality. Please see Master Response 35 - Discharge to South Fork Wolf Creek.

At the time any sampling for NPDES discharge permitting is conducted in accordance with permits required from the Central Valley Regional Water Quality Control Board (see April 4, 2022 comment letter from the Water Board, Agency Letter 5), additional fish bioassay studies may be

necessary. However, the existing fish bioassay results do not have any bearing on the finding of significant impacts from the project related to water quality.

## Response to Comment Grp 8-137

The ACZ lab reports are, in fact, provided in their entirety in the appendices to the EMKO report in Appendix K.2 of the DEIR. As noted in the responses above, the holding times and related notations are either not relevant to the analyses conducted or have no bearing on the impact analysis in the DEIR.

**Re: Comments on the Draft EIR for the Idaho-Maryland Mine Project**

From: David M. Chambers, Ph.D., P. Geop.

**Background**

David Chambers has 40 years of experience in mineral exploration and development – 15 years of technical and management experience in the mineral exploration industry, and for the past 30+ years he has served as an advisor on the environmental effects of mining projects both nationally and internationally. He has Professional Engineering Degree in physics from the Colorado School of Mines, a Master of Science Degree in geophysics from the University of California at Berkeley, and is a registered professional geophysicist in California (# GP 972). Dr. Chambers received his Ph.D. in environmental planning from Berkeley. His recent research focuses on tailings dam failures, and the intersection of science and technology with public policy and natural resource management.

**Grp 9-1**

**OVERALL COMMENT**

This is a rather unusual mine project proposal, a request for an 80-year operating permit, in that most regulatory agencies would consider the level of information presented for this environmental review of the project sufficient only to consider this as a proposal for advanced exploration, not for mine development. This mine development proposal lacks the economic and environmental data necessary to evaluate a full mine development proposal.

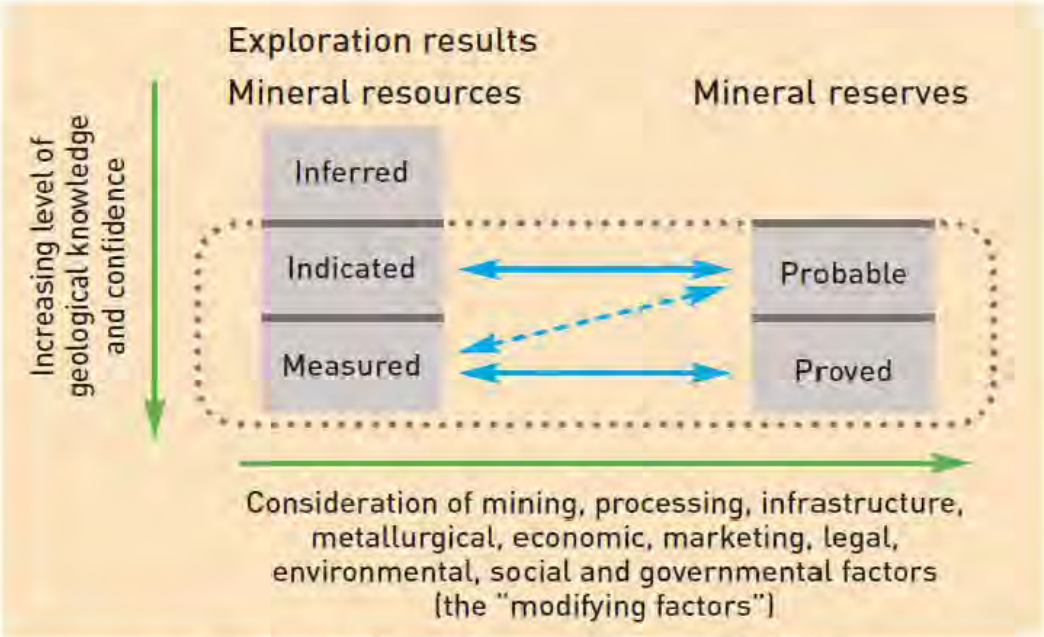
**Grp 9-2**

Unlike a typical mine that is being proposed for production, the Idaho-Maryland mine; (1) does not have an identified mineral reserve, or even a mineral resource; (2) the drilling core is not sufficient to provide the necessary information on the geochemistry of the waste rock and tailings; and, (3) there is no surface water-quality modeling. These are all elements that are critical in evaluating the potential impacts of a proposed mine.

As a result, it is not known whether the mine waste could leach contaminants into ground and/or surface waters. The design details of the "engineered fill" facility have yet to be done, so it not known if the proposed design is geotechnically sound. In addition, the long-term closure costs for the mine have not been analyzed.

Page #2

**SECTION-SPECIFIC COMMENTS**



**3.6 Project Objectives**

In order to have a credible mine proposal, a minimum amount of ore must be identified to warrant the economic investment to open a mine. It is possible that a mining company has enough capital to self-fund the hundreds of millions of dollars necessary to bring a mine property like Idaho-Maryland to the point where it is ready to produce its first ounce of gold, but this is seldom the case. And even if this were the case, a responsible board of directors would require a thorough economic analysis before committing this level of funding for a project.

A mineral property with no current mineral resources or mineral reserves has been described by the Canadian National Instrument 43-101 policy as an "early stage exploration property" (OCS 2011). This is the case with the Idaho-Maryland property's latest 43-101 compliant technical report (Rise Gold 2017).

A mineral resource is a concentration or occurrence of solid material of economic interest. A mineral reserve is the economically mineable part of a measured and/or indicated mineral resource (ICMM 2013). The figure below has presented in approximately this same format for quite some time as a way to illustrate how the concepts of mineral resource and mineral reserve are related – technically, economically, and legally.

Grp 9-3

***Classification of Mineral Resources & Reserves (ICMM 2013)***

Grp 9-4

Rise Gold does not have enough drill samples to satisfy the requirements to meet any of the mineral resource or reserve definitions described in the Classification of Mineral Resources & Reserves. This same lack of an adequate number of drill samples also results in the lack of data required to adequately characterize the geochemistry of the waste rock and tailings that will be produced, or to supply test data on the leachate from this waste that would allow modeling of potential impacts to surface water.

Page #3

**Geochemistry of the waste rock**

The projected waste rock geochemistry analysis is summarized in the EIR Appendix K.2: Groundwater Hydrology and Water Quality Analysis Report for the Idaho-Maryland Mine Project Nevada County, California, EMKO Environmental, February 2021.

In Table 4-5 (below) from Appendix K.2, it is predicted that the 96% of the waste rock will produced will be Meta-Andesite.

***Table 4-5 Estimated Daily Barren Rock Production***

| Material Type | Tons per Day | Percent of Material Produced |
|---|---|---|
| Meta-Andesite | 481 | 96 |
| Altered Meta-Andesite | 12 | 2 |
| Diabase | 5 | 1 |
| Serpentinite | 2 | 1 |
| **TOTAL** | **500** | **100** |

Rise completed 19 drill exploration drill core holes, totaling 67,500 linear feet, from 2017-2019. From this drill core, Benchmark Resources collected six drill core samples that it used to characterize the geochemistry of the waste rock. These samples are listed in Table 4-6.

Meta Andesite, which constitutes 96% of the waste rock to be mined, was taken from three intervals of drill core – samples MA-1, MA-2, and MA-3. Sample MA-1 was from the near surface rock 167' - 177' below the drill level, so it not representative of most of the Meta Andesite that will be produced from mining, which will occur at much greater depth. As a result, the geochemical predictions for approximately 96% of the waste rock to be produced comes from one 10-foot interval of drill core (Sample MA-2 from 3959.7 ' to 3969.7'), and one 1-foot sample (MA-3 from 3265' to 3266').

***Table 4-6 Core Samples Collected by Benchmark Resources***

| Sample Name | Description | Date | Time | Bag # | Hole # | Elevation Interval |
|---|---|---|---|---|---|---|
| MA-1 | Meta Andesite/Porphyrite | 29/10/2019 | 10:45 AM | Y973551 | I-19-13 | 167'-177' |
| MS-1 | Meta Sediment/Porphyrite | 29/10/2019 | 11:00 AM | Y973560 | I-19-13 | 1,067'-1,077' |
| MA-2 | Meta Andesite/Porphyrite | 29/10/2019 | 11:05 AM | Y973594 | I-19-13 | 3,959.7-3,969.7 |
| MAA-1 | Meta Andesite Altered/Porphyrite | 29/10/2019 | 11:20 AM | core box | I-19-13 | 3,357'-3,360' |
| S-1 | Serpentinite | 29/10/2019 | 11:25 AM | core box | I-18-11 | 4,725.6'-4,725.7' |
| MA-3 | Meta Andesite Altered/Porphyrite | 29/10/2019 | 11:45 AM | core box | I-18-10 | 3,265'-3,266' |

Another way to describe this is that the geochemical characterization of the 2 million tons of waste rock produced during the first 11-years of mining, and nominally the waste rock production from the entire 80-life of the proposed permit, is represented by these two samples, which come from a total of 11 feet of drill core.

Page #4

***Australian Guidance on Sample Numbers (adapted from Australian Government Department of Industry, Tourism and Resources, 2007 (GARD Guide Table 4-5)***

| Mine Phase | Number of Samples | Description |
|---|---|---|
| Exploration | (1) Prospect Testing – Include sulphur in list of elements being analyzed for all samples tested; include the full range of pathfinder elements as defined by ore deposit/exploration model; collect and record mineralogical data as per exploration/ore deposit model; where the geology of the deposit is known include static testing of at least 3 to 5 representative samples of each key material type (i.e., lithology, alteration type); analysis of ground water and surface water for acidity and representative pathfinder elements.<br>(2) Resource Definition – All samples tested for sulphur and representative samples tested for mineralogy as per ore deposit model. **Static testing of at least 5 to 10 representative samples of each key material type. *(emphasis added)***<br>Collect groundwater and surface water data. Surface water and groundwater analysis to include acidity as well representative metal ions.<br>All testing to include QA/QC samples. | By the end of the resource definition phase, there should be adequate information to accurately characterize the ARD potential of the ore body (high and low grade), although further test work will normally be required to characterize the ARD potential of waste rock and ore and hence tailings. |
| Pre-Feasibility | **Static testing of several hundred representative samples of high and low grade ore, waste rock and tailings**, the number dependent on the complexity of the deposit geology and its host rocks. ***(emphasis added)***<br>All drillhole samples analyzed must include sulphur analysis and identified representative metal ions. Sampling density is dependent on complexity of ore deposit and host rock geology interval of representative drill holes but should be restricted to single rock units or lithologies - include minimums.<br>**Kinetic testing of at least 1 to 2 representative samples of each material type. *(emphasis added)***<br>Surface water and groundwater analysis to include acidity as well as pH, EC and representative metal ions, including Al, Fe, Mn.<br>All testing to include QA/QC samples. | Where required, the number of samples must be sufficient to populate a "resource" block model of the ore and host rocks that will be affected by mining with a reliable distribution of NAPP[1] data (e.g., acid producing potential (APP), sulphur and acid neutralizing capacity (ANC) (or NPR data) on ore, waste rock and wall rock. |
| Mine Planning, Feasibility and Design | Where required, additional static testing as required for block waste resource model refinement – **increase density of NAPP (or NPR) characterization. *(emphasis added)***<br>Inclusion of confirmatory testing (e.g., NAG testing for comparison to NAPP (i.e. APP, or sulphur, and ANC) for metalliferous deposits; and mineralogy or NPR values).<br>Continuation of kinetic testing.<br>Upgrade drillhole database and waste resource model for new ore positions.<br>All testing to include QA/QC sample(s). Apply QA/QC to all analyses, not only ore. Include wall rock. | Data set must be sufficient to assess ARD potential to support a management plan. If data are insufficient, additional testing will be required. |

Page #5

The widely accepted source of guidance for determining the number of samples for acid-drainage/metals-leaching prediction is the Global Acid Rock Drainage Guide (GARD 2018), published by the International Network for Acid Prevention. The GARD Guide has adopted the Australian Guidance on Sample Numbers for determining the number of samples needed to determine acid-drainage/metals-leaching potential (GARD Guide Table 4-5).

The number of samples used to predict the leaching potential of the tailings and waste rock for the proposed Idaho-Maryland Project does not meet even the lowest level of these criteria. The number of samples analyzed for this proposal would not even meet the requirements for the Exploration stage of sampling, let alone the Mine Planning, Feasibility and Design phase, which is the level of development being proposed for the Idaho-Maryland Project.

**3.7 Project Components– Water Treatment**

There is no discussion, or disclosure, of the operational water quality treatment needs or processes. The EIR merely requires that the applicant apply to the Regional water Quality Control Board for a discharge permit. The water quality discharge that will be required by the discharge permit should be disclosed in the EIR so that the public is able to assess and comment on the potential impacts. To simply assert that water quality standards will be met is not sufficient for reviewers to assess either the adequacy of the water treatment methods proposed, or the adequacy of the standards proposed for the discharge permit.

**Grp 9-5**

This completely circumvents any discussion or analysis of what the contaminants of potential concern might be, what contaminants would be monitored, what treatment methods are available, and where monitoring would take place. This information should all be disclosed in the EIR.

In addition, a Monitoring Plan should be included. The Monitoring Plan should incorporate all elements of monitoring, including surface water, ground water, air, and noise sampling. Sampling locations, frequencies, and constituents should be disclosed/discussed in the Monitoring Plan, and summarized in the EIR.

**Grp 9-6**

**3.7 Project Components – Backfill**

It is noted that approximately 500 tons/day of tailings will be backfilled into the mine as cemented paste. The technical details of the process are contained in "Desktop Study of Cemented Paste Backfill, ITASCA Denver, Inc. February 24, 2020." In this report it is noted that no tests on the leaching characteristics of tailings have been performed, but that testing would be done when a cement had been selected. Even though the backfill is unlikely to turn acidic, the potential for neutral leaching of contaminants like arsenic need to be investigated.

**Grp 9-7**

The answers to several critical questions that should be addressed in Chapter 3 of the EIR are: (1) the grind size of the tailings used for backfill; (2) the type and amount of cement to be used; and, (3) the results of leach tests on the backfill.

This information should have been available for the EIR, and is another data gap in the EIR.

**3.7 Project Components – Engineered Fill Transport**

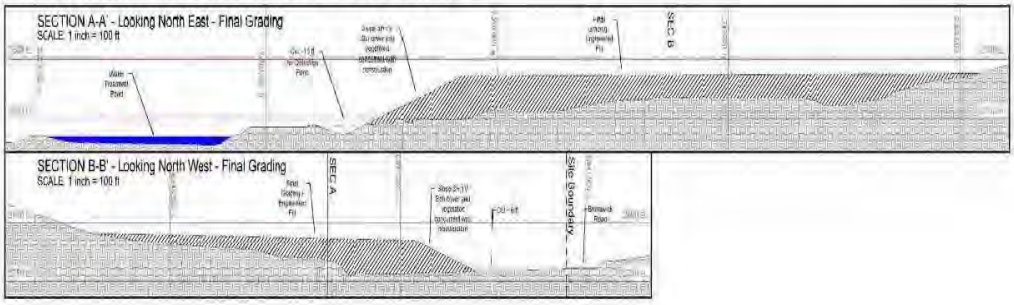
Even though this is nominally the section about the transport of the waste material, most of the technical information on the Engineered Fill is presented here.

**Grp 9-8**

The mine waste that is not backfilled into the mine will consist of 50% tailings (rougher tailings from flotation separation in the mill), and 50% waste rock from the mine. Approximately 4 million tons of waste would be placed at two sites near the mine during the first 11-years of mining. The number of samples utilized in the leach tests of this waste is not sufficient to properly characterize the contaminants

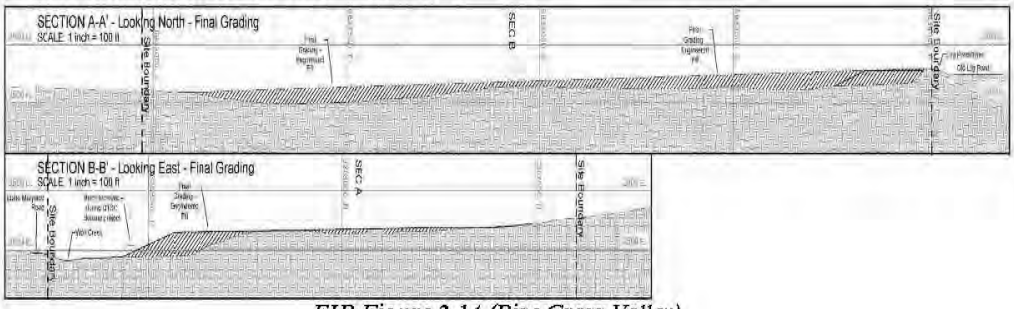
Page #6

that may be leached from the waste. Comparing the number of samples cited in the EIR to the sampling guidelines of the GARD Guide demonstrate the insufficiency of the existing tests.



In addition to testing for the contaminants that may come from the waste, as the term "engineered fill" implies, this will be an engineered mine waste facility. The EIR, and its supporting documents, imply that the required engineering analysis will be done at some future time, but provide virtually no engineering analysis or design specifications for these waste facilities as a part of the EIR.

It is stated in the EIR that, "*Engineered fill would continue to be placed, graded, and compacted in a series of lifts …*" The only drawings of the cross sections of the waste facilities in the EIR are from Rise Grass Valley, not an engineering company, and seems to show the mine waste being deposited as end-dump layers that cannot be compacted to generate further stability, not horizontally-deposited layers that could be compacted.



The new mine waste will be placed on top of portions of existing mine waste, which could provide a plane of weakness that could provide an additional failure plane for the significant weight of rock that will placed on top of it. The Brunswick facility is projected to be up to 90 feet in height, and the Centennial facility up to 70 feet high.

**Grp 9-9**

BRUNSWICK INDUSTRIAL SITE - SECTIONS

CENTENNIAL INDUSTRIAL SITE - SECTIONS

*EIR Figure 3-14 (Rise Grass Valley)*

Page #7

There is no technical report to provide the detail needed to evaluate the geotechnical viability and safety of these facilities. The potential for this waste to fail under static or seismic loading needs to be professionally evaluated by a qualified engineering contractor. It would be inappropriate to issue a permit for the construction of these waste facilities without proper engineering analyses. To illustrate what could happen, the picture in Photo 1 comes from a waste rock pile at a Nevada mine that failed due to inadequate engineering. While not catastrophic, such failures can cause significant environmental and economic damage.

***Photo 1: Waste Rock Dump Failure at the Gold Quarry mine (2005)***

The seismic reports discussed in the Geology section of the EIR are not up to date, and even if updated would not meet the requirements for a probabilistic seismic site analysis. Mine waste facilities must be designed to withstand much larger seismic events than required by typical seismic building codes because of the long expected life of the water facilities. According to information provided in the Brunswick and Centennial Industrial Site Geotechnical reports (EIR Appendices H.1 and H.4), a probabilistic and/or deterministic seismic assessment has not been done for the Idaho-Maryland site.

**Grp 9-10**

In the geotechnical report for the Centennial Industrial Site the mine waste to be used as engineered fill is described as; "*We understand that proposed foundation structures will be constructed on import fill material that will primarily consists of medium dense granular soil composed of silty or clayey sand/gravel, with possible rock fill at depths.*" The term "medium dense granular soil composed of silty or clayey sand/gravel" is not an adequate description of the tailings. Tailings, at a 75 um grind size, the most likely choice for grind size based on the flotation recovery testing done by McClelland Labs, are termed "silt" (see EIR Appendix H.4, Table 5.1-1, Particle Size Gradation, Historical Sand Tailings).

Page #8

**Grp 9-11**

With an equal ratio of tailings to waste rock in the engineered fill, not only is a careful analysis of the geotechnical properties of the tailings important, and currently lacking, but how these two fill sources are mixed is also critical, since the tailings and waste rock have very different geotechnical properties. These analyses are lacking in the EIR and its supporting technical reports.

**Grp 9-12**

In the EIR, it is also proposed that an alternative for placing the mine waste in the proposed facilities is selling the waste in the local marketplace as fill material. There are several issues that make this proposal unlikely. First, there is liability associated with mine waste. Even if the waste is purported to be contaminant-free, and this waste is associated with mining sulfide mineralization that can release metal contaminants, it is seldom possible to guarantee that all of the waste will be contaminant-free. According the laboratory analysis for the six waste rock samples analyzed for Acid-Base Accounting, the sulfide sulfur content of the waste rock varies from 0.04 - 1.78 % Sulfide Sulfur (EIR Appendix K.2, EMKO 2021, Table 4-8 Tailings & Barren Rock Samples - ABA Results). There is significant variability in the amount of sulfide sulfur, and significant amount of sulfide sulfur (1.78%), recorded in the very limited number of waste rock samples tested. If any of the waste sold as clean fill should cause a problem, the sellers of that material, and the company that produced that material, would likely be legally liable. Just the possibility of legal entanglement keeps virtually all mining companies from selling its waste rock or tailings, and is very likely to make it very difficult to find an independent distributer that is willing to assume this risk.

**Grp 9-13**

A second issue is one of logistics. The mine waste is produced at a constant rate – 1,000 tons per day, 365 days/year, for the life of the mine. Markets for fill material are typical episodic. For example, there is much more fill material placed during the summer than during the winter. In order to handle surges in the demand for fill material, temporary storage for a significant amount of material would be required by a vendor of this material. If the mining company is going to provide this service itself, then the storage facility should be evaluated as a part of the mine proposal. If the material is to be sold to an independent user, then the viability of that operation should be demonstrated with at least a contract that someone is willing to accept 1,000 tons/day of mine waste.

**3.7 Project Components – Reclamation Plan**

Most reclamation plans submitted as a part of a mine proposal are largely conceptual in nature, including the reclamation plan accompanying this EIR. However, for those tasks that can be clearly identified as being necessary for mine closure, these tasks should be described with enough detail that the engineering feasibility and cost can be analyzed.

In order to protect the public from incurring the costs associated with an unplanned mine closure, or bankruptcy, the funds should be available to public agencies that are sufficient for those agencies to take over and complete reclamation of the mine, and to perform any water treatment that may be required.

**Grp 9-14**

At the Idaho-Maryland Mine, it is known that mine openings must be closed, drains must be prepared to collect the seepage that has been coming from the mine, and that will presumably resume after mine closure, and that the mine waste facilities can be closed and safe configuration. However, there are no reclamation engineering specifications, work plans, or cost estimates made for the EIR.

The potential costs for post-closure water treatment, if required, should also be included. However, there is insufficient information on seepage water quality to conduct this analysis.

Financial Assurances for mine closure runs tens to hundreds of millions of dollars, so ignoring these costs puts taxpayers at significant risk of miscalculation at a later date. Because these sums are so substantial, the public should be informed about these costs, and how the costs were estimated.

This is a significant omission in the EIR.

Page #9

**4.8.2 Existing Environmental Setting – Groundwater Occurrence in Mine Workings**

**Mine Flooding and Worker Safety**

In the discussion of the Union Hill Mine, it is noted, "*The Union Hill Mine workings are within 95 feet to 180 feet of workings of the Brunswick Mine at three to four different levels. During the post WWII period, the combined Idaho-Maryland Mine workings were completely dewatered. In 1956, the water level at the Union Hill Mine was reported to be within 20 feet of the top of the shaft, suggesting that the complete dewatering of the adjacent mine workings resulted in no more than 10 to 20 feet of water level decline in the Union Hill Mine.*"

There are two important points to note in this discussion, (1) the Union Hill Mine is very close to the Idaho-Maryland at several levels; and, (2) there has been a possible weak hydraulic connection between the two mines, which is only logical.

**Grp 9-15**

The EIR notes that the Union Hills Mine will not be dewatered. The EIR suggests there is no significant hydraulic connection between the mines, but the discussion from the EIR quoted above suggests there could be some connection, and what is not known is whether this hydraulic connectivity could increase in the future.

There is no discussion in the EIR of the potential impacts for the Idaho-Maryland Mine if flooding were to occur during mining. From ITASCA Figure 2-3 (attached as the last page of this document), it can be seen there are extensive abandoned mine working above and adjacent to the Idaho-Maryland mine that will remain flooded after the Idaho-Maryland is dewatered.

If a conduit between these two mine were to open, for instance due to the widening of a fracture related to blasting vibrations or a seismic event, the flood of water into the Idaho-Maryland could be rapid and catastrophic for anyone working in the mine.

This issue must be thoroughly addressed before anyone is permitted to enter the dewatered mine.

**4.8.4 Impacts and Mitigation Measures – Water Within Underground Mine Workings**

**Geochemistry of the tailings**

Even though this is nominally the section about the underground mine water, most of the technical information on the geochemistry of the tailings samples is presented here.

Approximately 50% of the mine waste, also referred to as "engineered fill", disposed on the surface will be tailings. The geochemistry of these tailings is important because meteoric waters will infiltrate through the waste, and any leachate products will end up in groundwater, and potentially surface water.

**Grp 9-16**

Tailings produced in the milling process are generally homogeneous because the physical and chemical processing of the ore remains relatively constant, and the ore is typically blended to maintain a consistent ore grade to facilitate gold recovery. Because of this, fewer tailings samples than waste rock samples are required for leach testing, but those testing samples must be representative of the tailings that will be produced during mine operation.

While Appendix K.2 states that the tailings samples were generated from a "46 kg metallurgical sample". The ore sample used to create the four tailings samples contained 1.6% Sulfur (EIR 2021, p. 4.8-46). The four tailings samples had a sulfur content of 0.06 – 0.12% Sulfur (EIR 2021, p. 4.8-46), with Net Neutralization Potential greater than 100 for all samples (EIR Appendix K.2, EMKO 2021, Table 4-8 Tailings & Barren Rock Samples - ABA Results).

The drill hole intervals this material came from is not stated in the EIR, nor is the time when the metallurgical sample was generated. Again, if an NI 43-101 compliant report that reported a mineral

Page #10

resource and/or reserve were available, this basic information would have required and would have been available for the EIR.

In Appendix K.2, EMKO notes that the four samples are of different grind sizes. The size of the tailings particles could have an effect on the rate of leaching. Smaller grain size leads to more rapid leaching of contaminants. Based on the results of the metallurgical testing, a final grind size is generally selected before geochemical testing is done, but a final grind size has not been selected for this project. The different grind sizes of the tailings could have an unquantified effect on the leach testing of the tailings samples.

**Grp 9-17**

Because the size specification has geotechnical and geochemical implications for both the tailings disposed on the surface, and cemented backfill in the mine, the size specification needs to be disclosed in the EIR. The limited test results available from preliminary tailings tests are not sufficient to make long-term predictions for the geotechnical stability or water quality implications of the tailings.

The method selected for leach testing the tailings and waste rock used distilled water, which is the least aggressive of the leach testing methods. For mining waste, waste rock and tailings, short-term tests typically use a weak acid solution for leach testing in order to simulate the generation of some acid in the waste due to sulfide decomposition. Long-term leach testing, which runs for months rather than hours or days, typically uses distilled water, because natural sulfide decomposition and the accumulation of oxidation products has sufficient time to stabilize.

***From Table 4-7 Tailings & Barren Rock Samples - Total Metals and DI-WET Results***

| Constituent | Test Type | Units | Tailings Samples | | | | Rock Samples | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | F-1 | F-2 | F-3 | F-4 | MA-1 | MA-2 | MA-3 | MAA-1 | MS-1 | S-1 |
| **METALS** | | | | | | | | | | | | |
| Aluminum | Total | mg/Kg | 16100 | 16300 | 16300 | 16300 | 23000 | 24400 | 31100 | 421 | 22900 | 41300 |
| | DI-WET | mg/L | 0.17 | 0.18 | 0.26 | 0.28 | 0.94 | 1.08 | 0.6 | 0.49 | 0.99 | 0.32 |
| Antimony | Total | mg/Kg | 0.2 | <0.2 | <0.2 | <0.2 | <0.2 | <0.2 | <0.2 | 1.1 | <0.2 | 0.6 |
